Gravitational Wave Astrophysics

Xian Chen (陈弦)

Astronomy Department/Kavli Institute of Astronomy and Astrophysics

Peking University

Email: xian.chen@pku.edu.cn

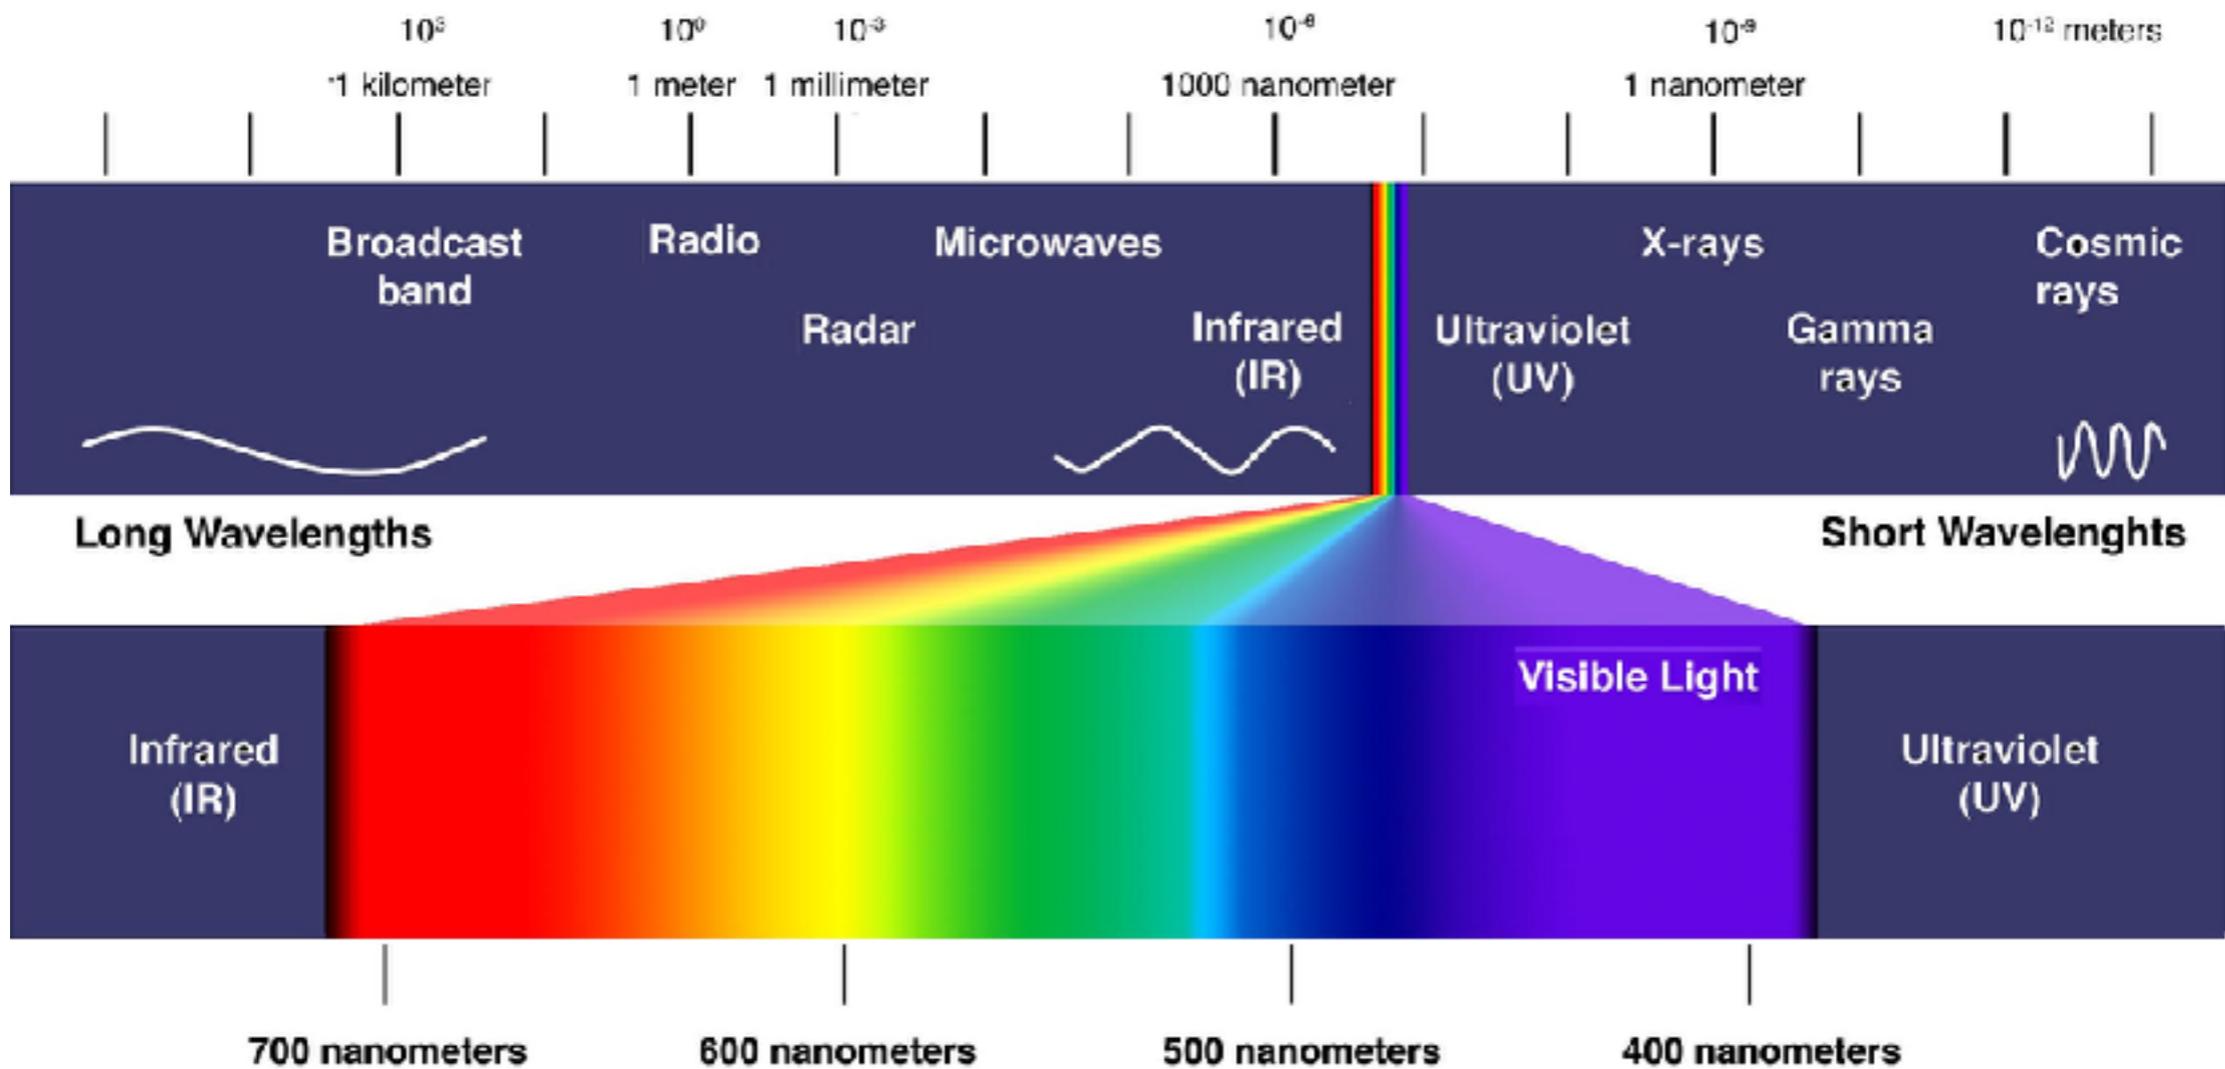

Outline

- Why do astronomers care about GWs?
- What kind of sources are out there?
- How do they form? (It is not obvious)
- What's next? (My own work)

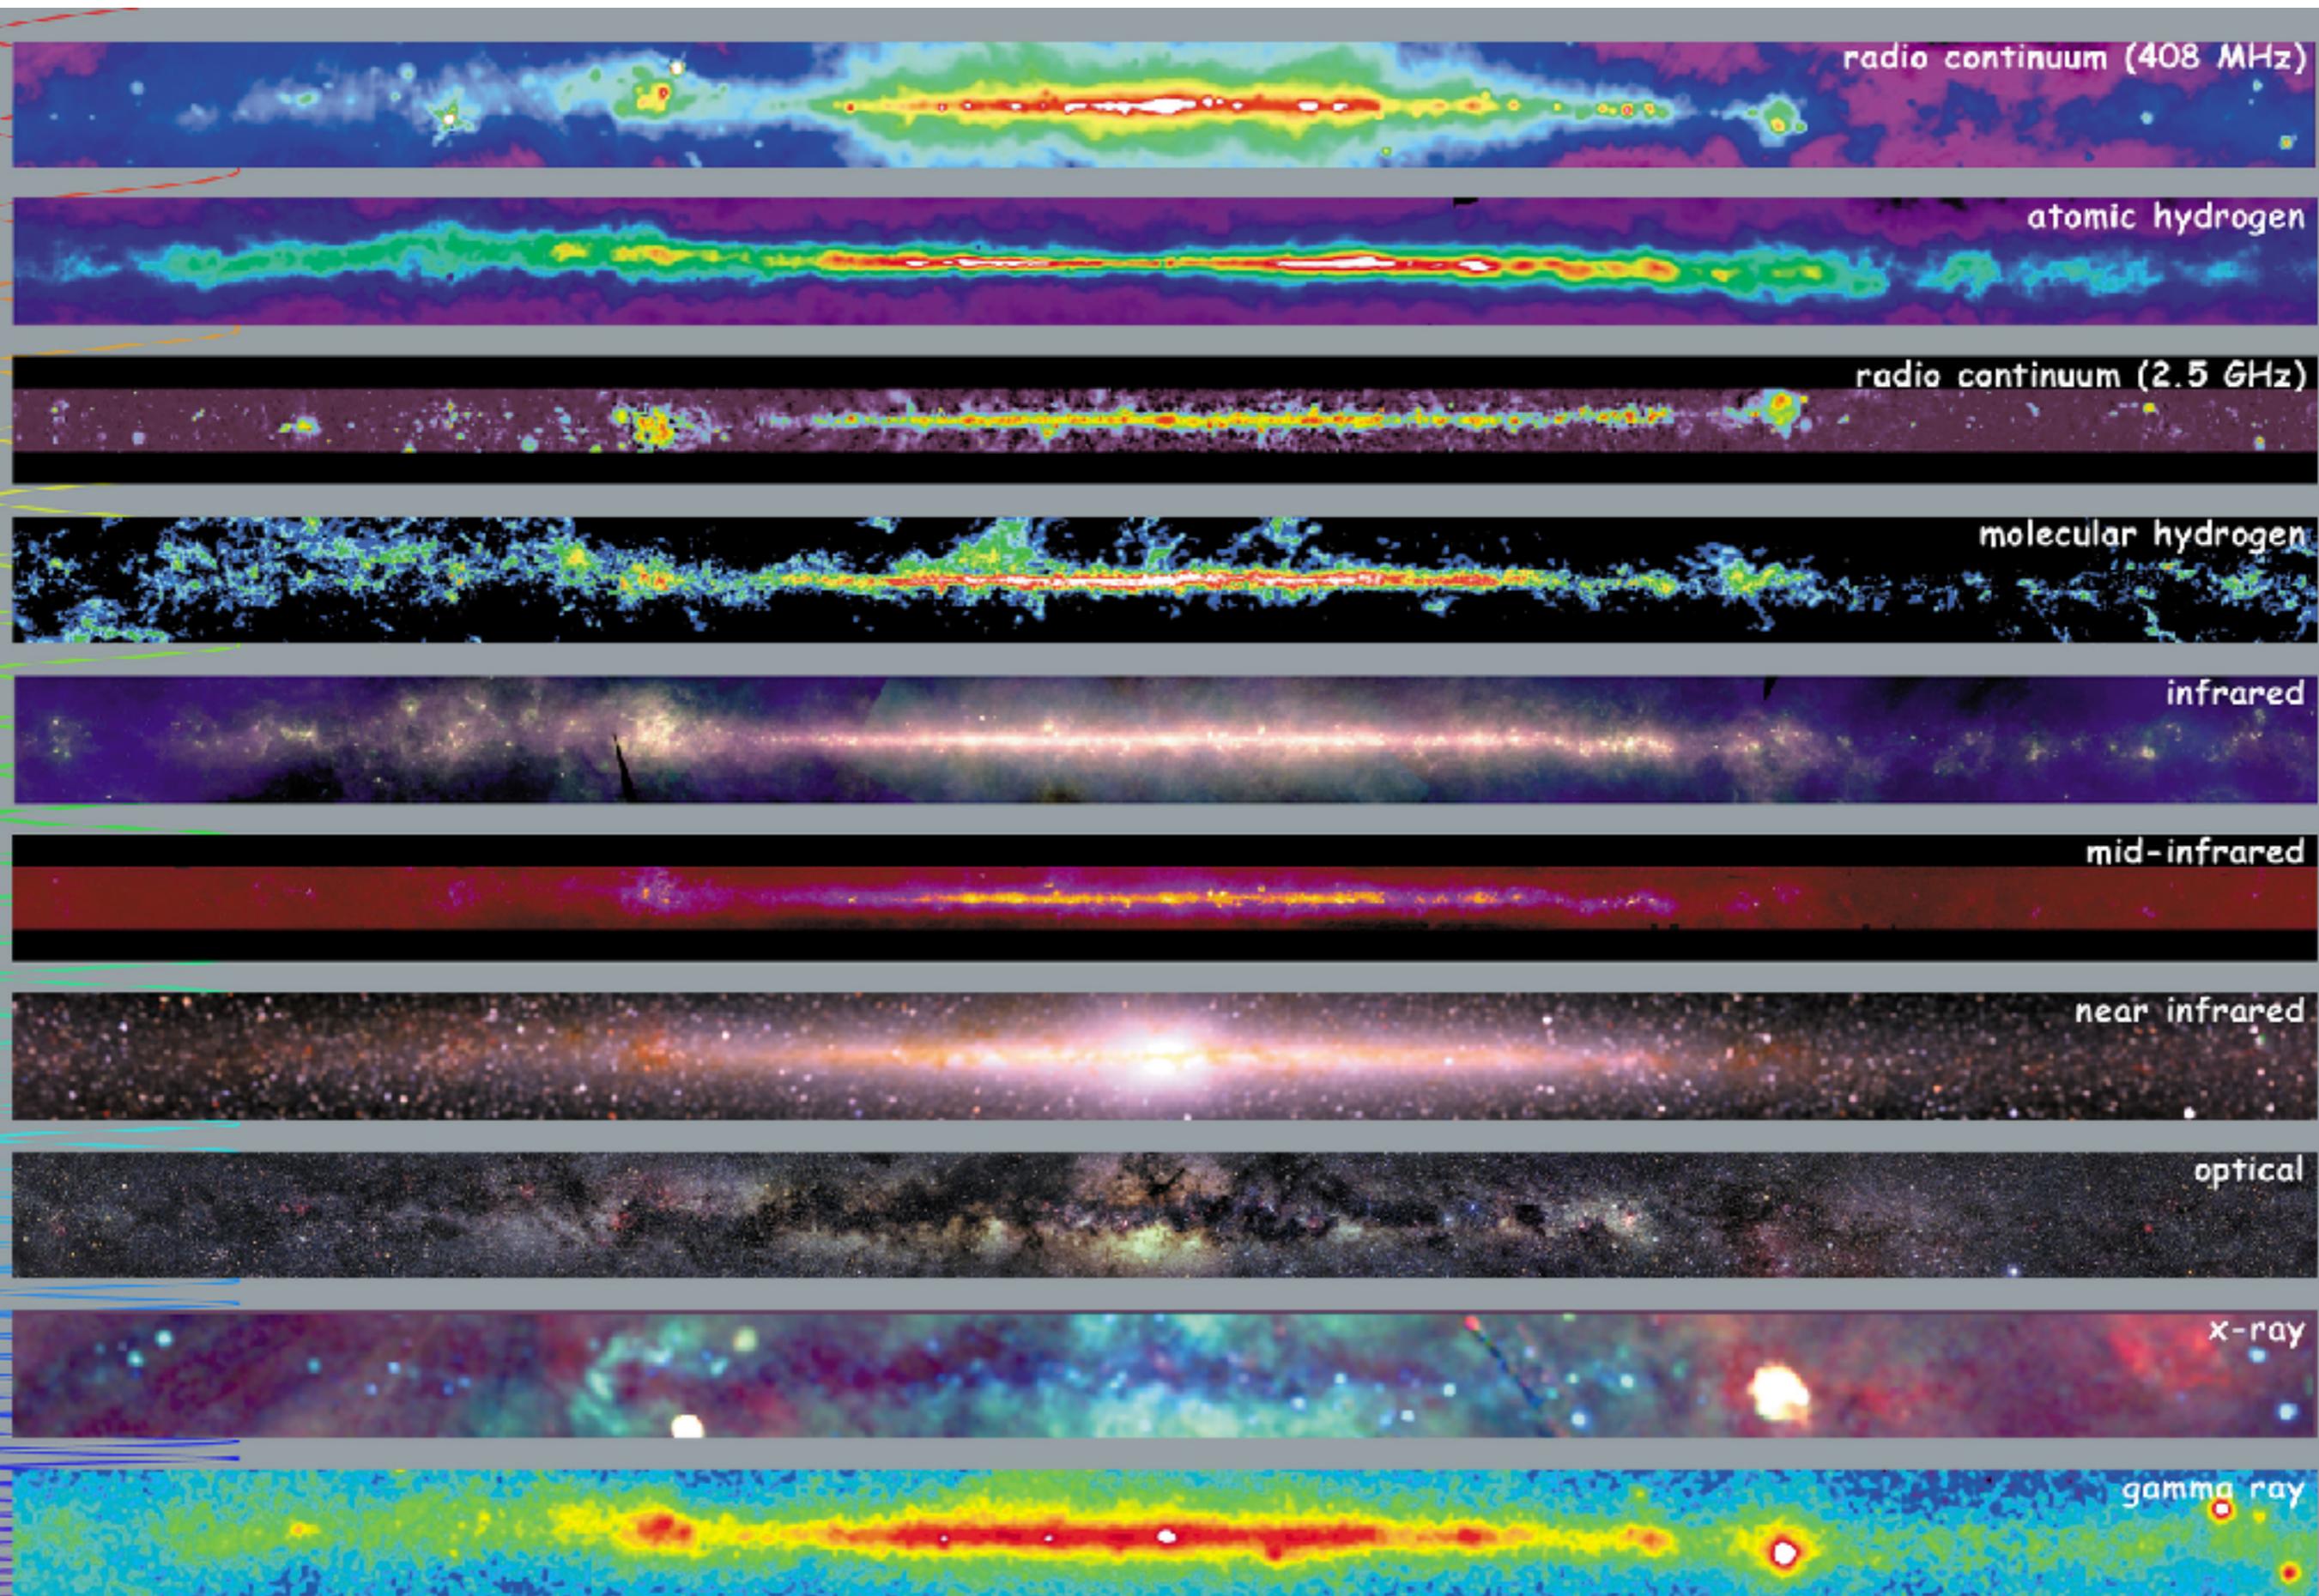

Why do we care: New Window

- Astronomers love new bands
 - For centuries: optical, stars

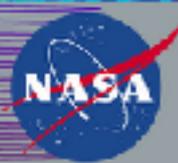

Why do we care: New Window

- Astronomers love new bands
 - **1910: electrometers, cosmic rays
 - **1930s: radio, quasars, pulsars
 - **1940: X-ray, X-ray binaries (neutron stars, black holes)
 - **1960s: microwave, cosmic microwave background
 - late 1960: gamma-ray, gamma-ray bursts (massive collapse, neutron star mergers)
 - **1970: neutrino, fundamental forces
 - 1990: infrared, Sgr A* is a supermassive black hole

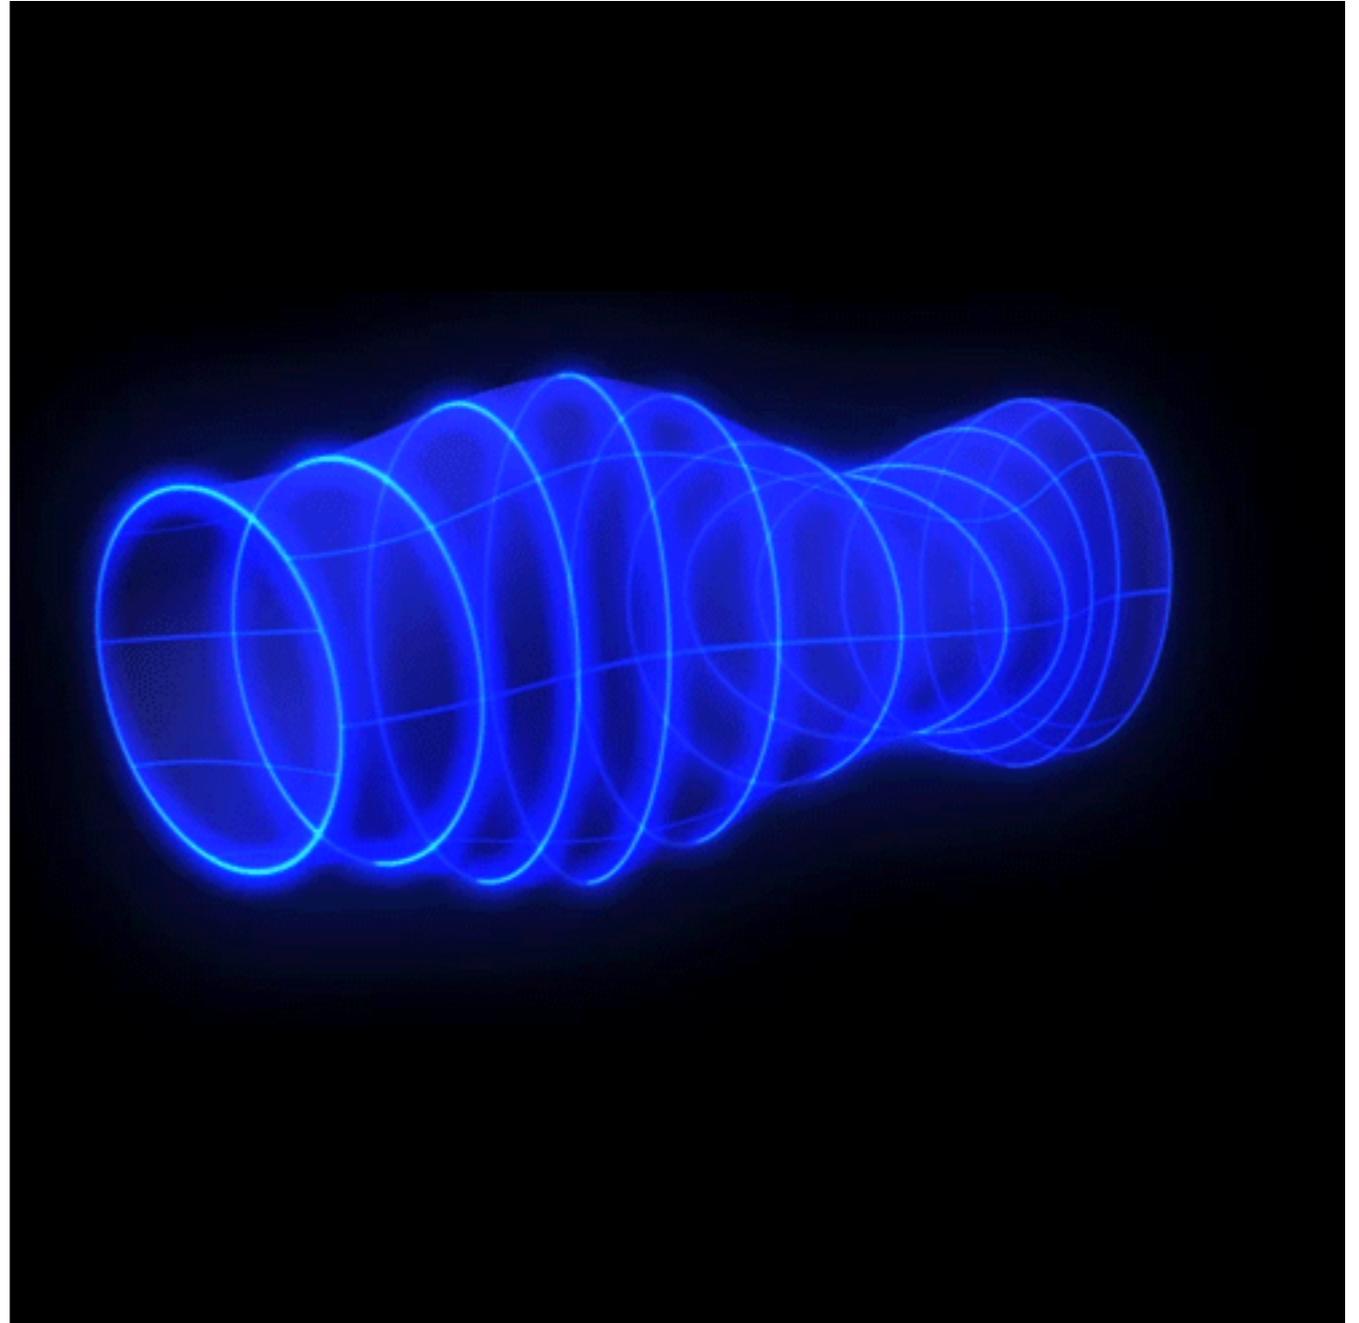

<http://arc.gsfc.nasa.gov/mw>

Multiwavelength Milky Way

Gravitational Waves

- Acceleration
 - Charge dipole: EM radiation
 - Mass quadrupole: GW

Why do we care: Advantages

(K. Thorne 1995)

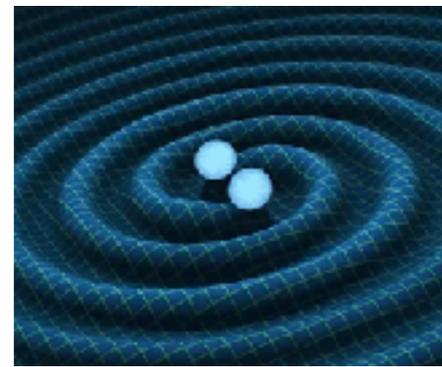

- GWs are not absorbed:
 - Light waves easily interact with atoms
 - GWs couple very weakly with matter (deep and far)
- GWs reveal matter in ACTION:
 - Acceleration of quadrupole moment $h \sim \frac{G}{c^4} \frac{\ddot{I}}{D}$
 - While light waves reflect thermal dynamical state of matter
 - Photos v.s. movies

Why do we care: Surprises?

(Credit: Pau Amaro-Seoane)

What are out there: Sources?

$$h \sim \frac{G}{c^4} \frac{\ddot{I}}{D}$$

$$h \sim \frac{m_1 m_2}{D a}$$

$$G \simeq 6.67 \times 10^{-8} \text{ cm}^3 \text{ g}^{-1} \text{ s}^{-2}$$

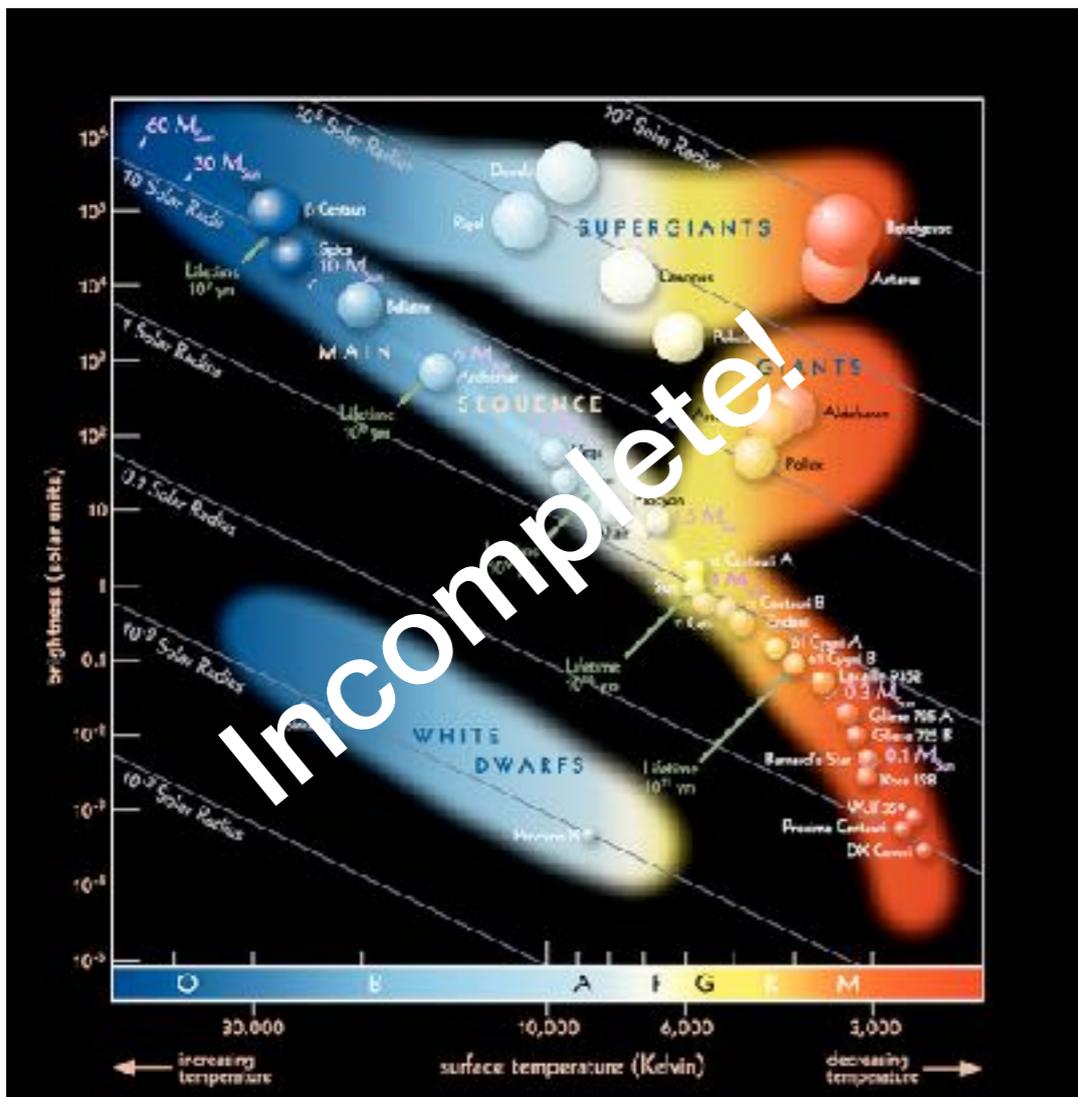

$$c \simeq 3 \times 10^{10} \text{ cm s}^{-1}$$

Imagin : Two test mass 10 m apart, each of 1 ton,

$$h \sim 10^{-40}$$

Astronomers know massive bodies

$$M_{\text{sun}} \simeq 2 \times 10^{33} \text{ g}$$

	Sun	White Dwarf	Neutron Star	Black Hole
Mass (Msun)	1	1	2	10
Radius (km)	7E+05	6E+03	10.0	30
M/R	1.4E-06	1.7E-04	2.0E-01	3.3E-01

Compactness of stellar objects

How do they sound?

$$f = \frac{1}{\pi} \sqrt{\frac{GM}{a^3}} \propto \frac{1}{M} \text{ because } a_{\min} \sim GM/c^2$$

Laser Interferometer Space Antenna

LISA

We are “Gravitational wave astronomy-Beijing”

LISA associate group

What's in LISA: **Compact** Binaries

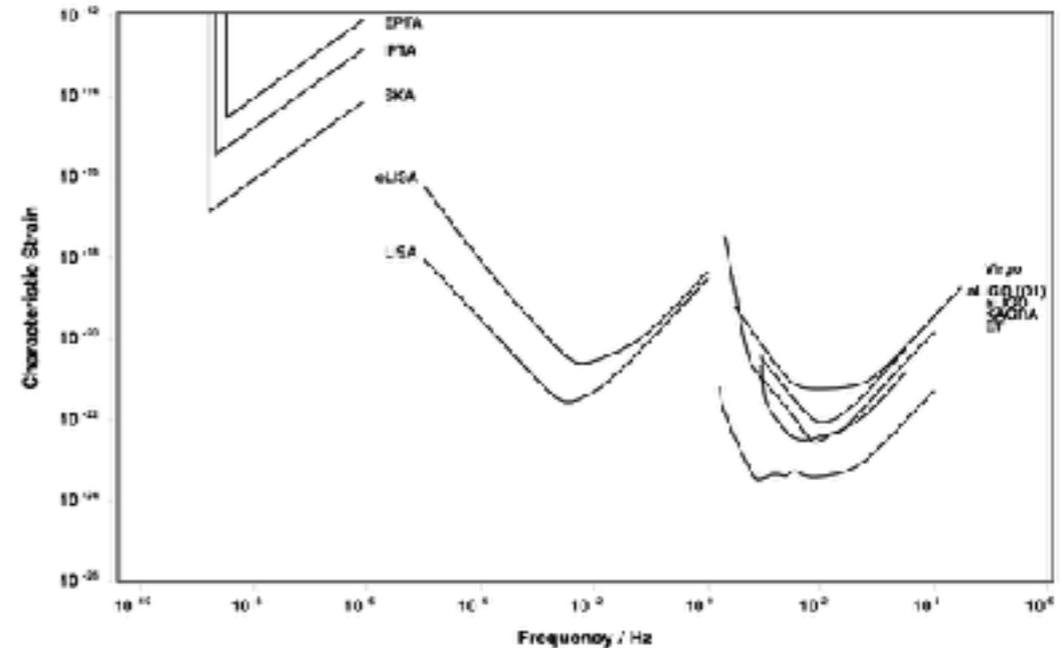

- WDs, NSs, SBHs, SMBHs
- Keplerian frequency \sim mHz

$$f = \frac{1}{\pi} \sqrt{\frac{G(m_1 + m_2)}{a^3}}$$

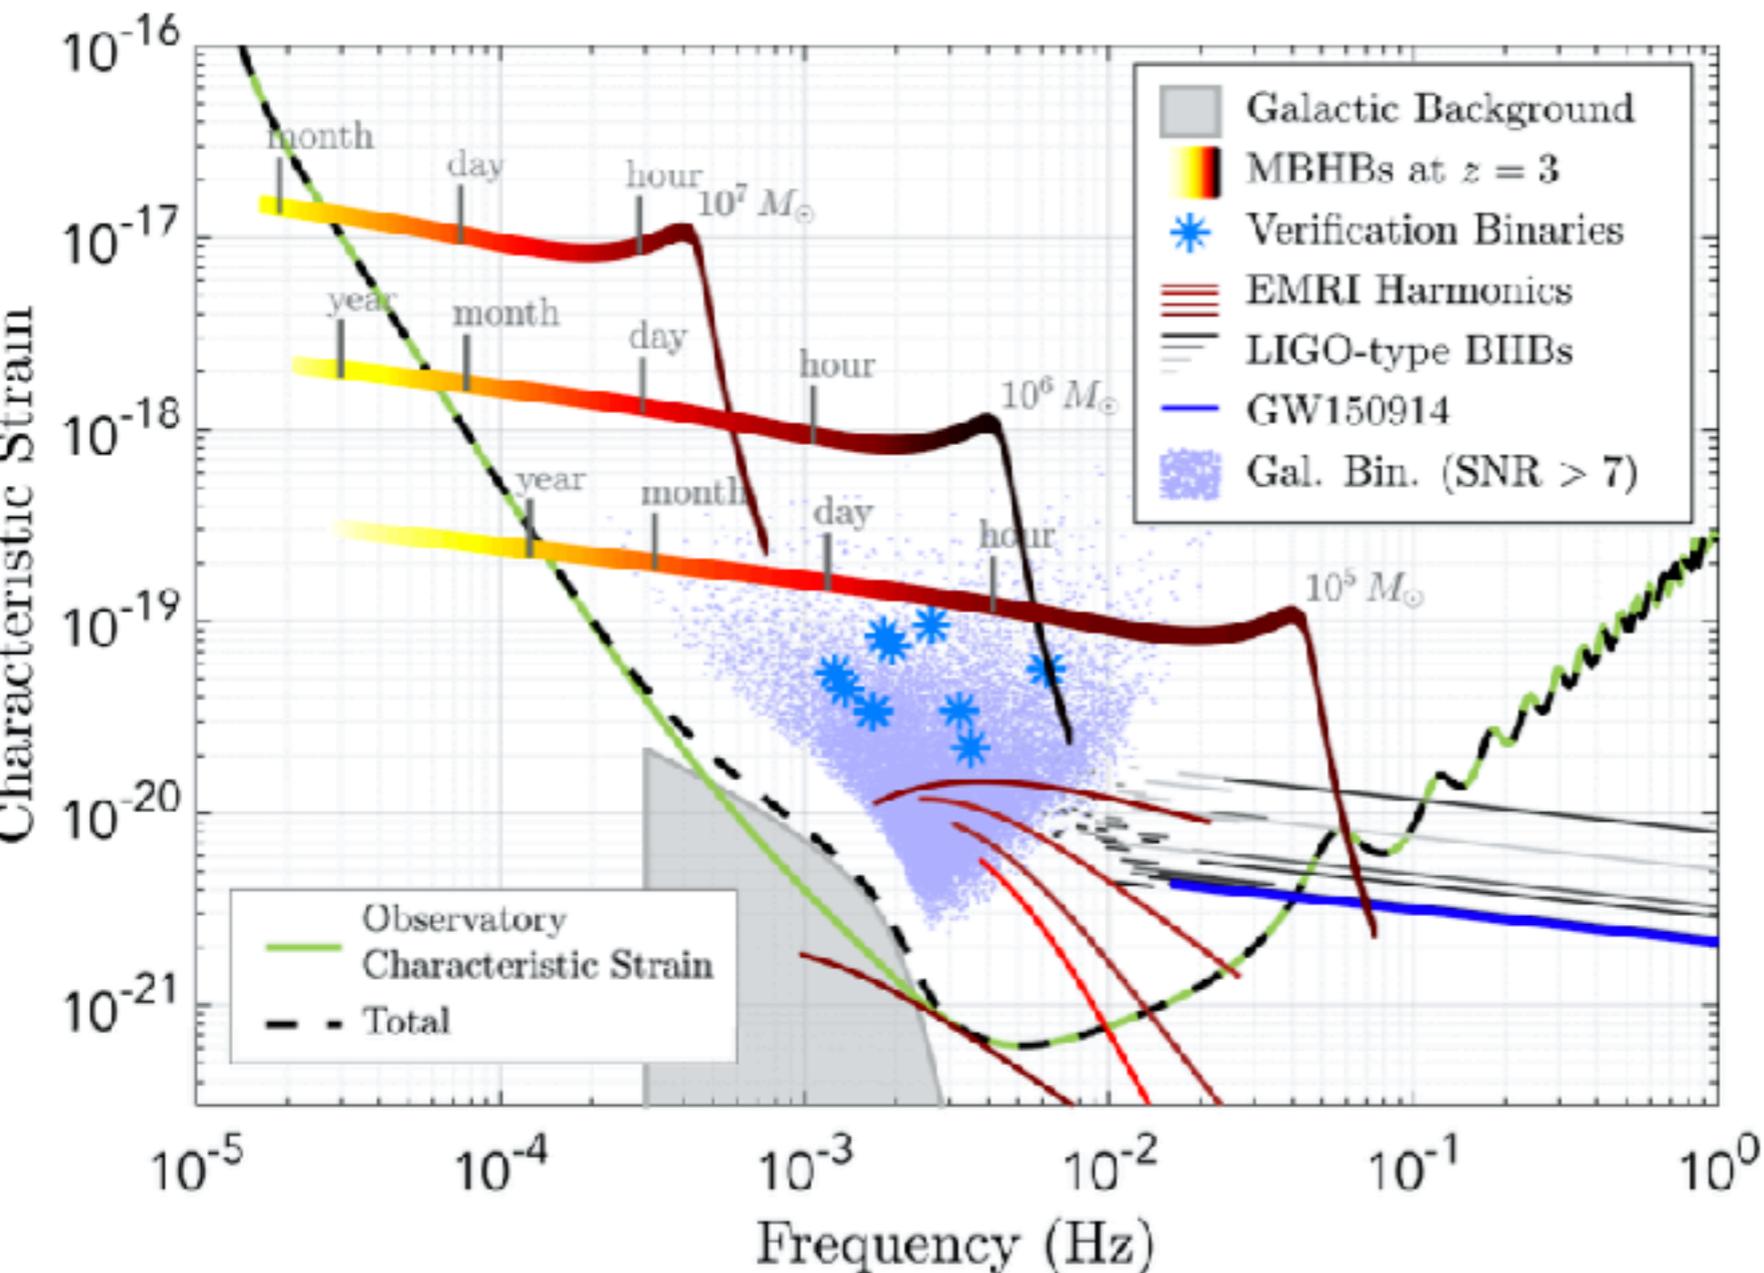

$$\text{WD/NS} \quad \simeq 2.00 \times 10^{-3} \left(\frac{m_1 + m_2}{1 M_\odot} \right)^{1/2} \left(\frac{a}{10^{-3} \text{ AU}} \right)^{-3/2} \text{ Hz}$$

$$\text{SBH} \quad \simeq 3.17 \times 10^{-3} \left(\frac{m_1 + m_2}{20 M_\odot} \right)^{-1} \left(\frac{a}{10^4 r_S} \right)^{-3/2} \text{ Hz}$$

$$\text{SMBH} \quad \simeq 2.00 \times 10^{-3} \left(\frac{m_1 + m_2}{10^6 M_\odot} \right)^{-1} \left(\frac{a}{10 r_S} \right)^{-3/2} \text{ Hz}$$

What are out there: A Bucket of Binaries

- Stellar binaries
 - WD-WD
 - SBH-SBH
 - NS-NS
- Supermassive Black Hole Binaries (SMBHBs)
- Extreme Mass Ratio Inspirals (EMRIs)

Formation: General Picture

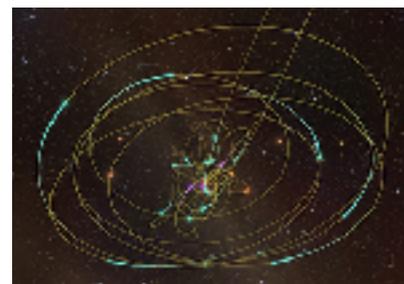

- Scales (in km)

- WD: 6000, NS: 10; SBH: 30, SMBH: $3e6$

- Galaxy: $3e17$; Mean stellar distance: $3e13$

- Globular cluster: $1e14$; Mean stellar distance: $3e11$

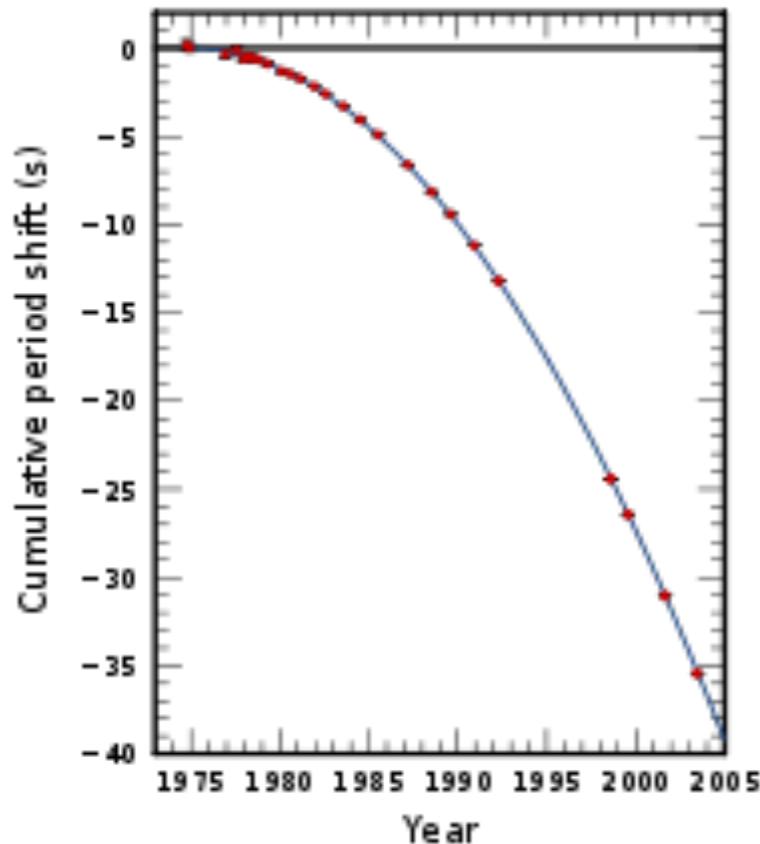

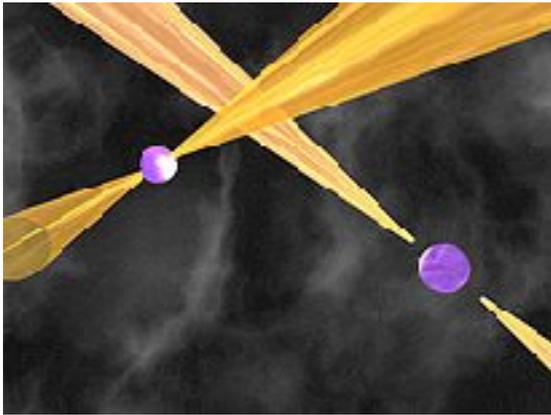

- Galaxy center: $3e13$; Closest distance (S2 star): $1e11$

- 10^{10} : Imagine two 1mm dust particles in Earth atmosphere

- Two bodies form close enough+lose energy efficiently (not GW rad.)

Formation: Stellar Binaries

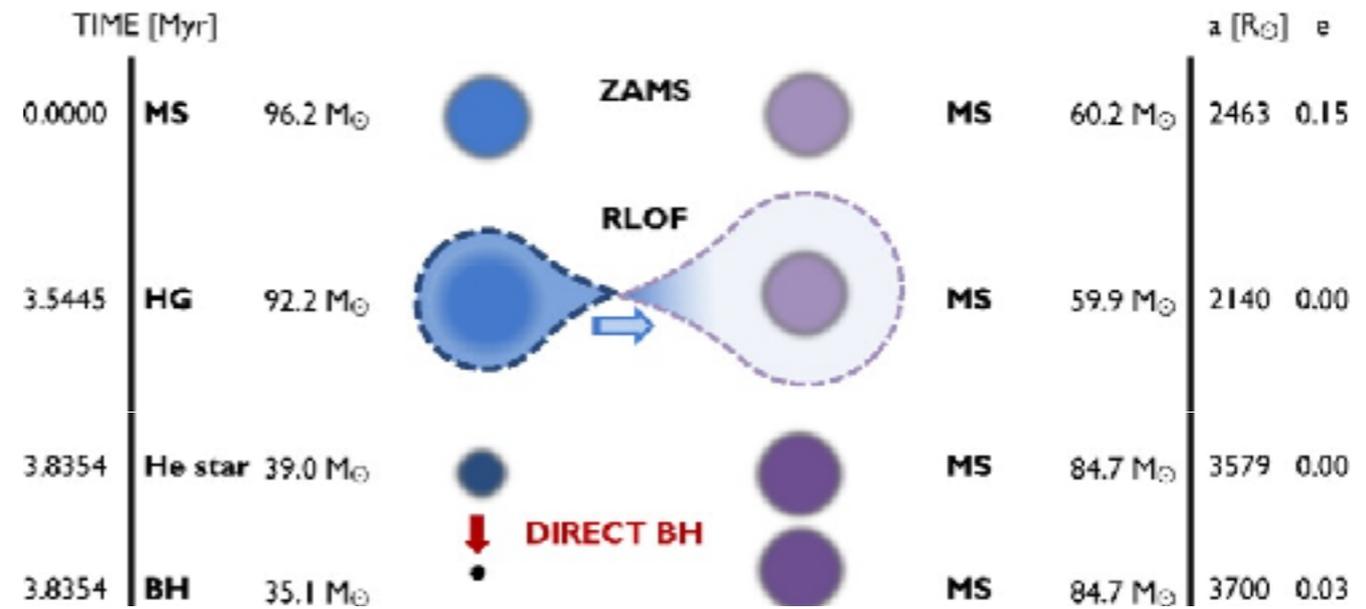

Taylor-Hulse pulsar

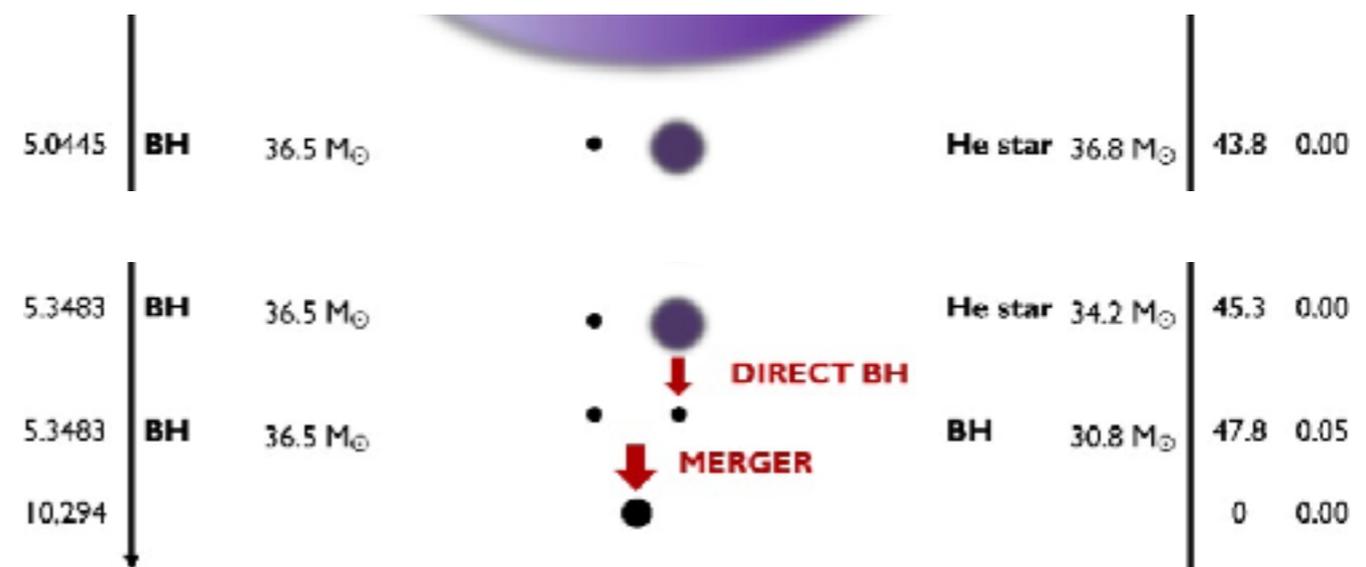

1993 Nobel Prize

Semi-major axis: 2×10^5 km

Decay time: 3×10^8 yrs

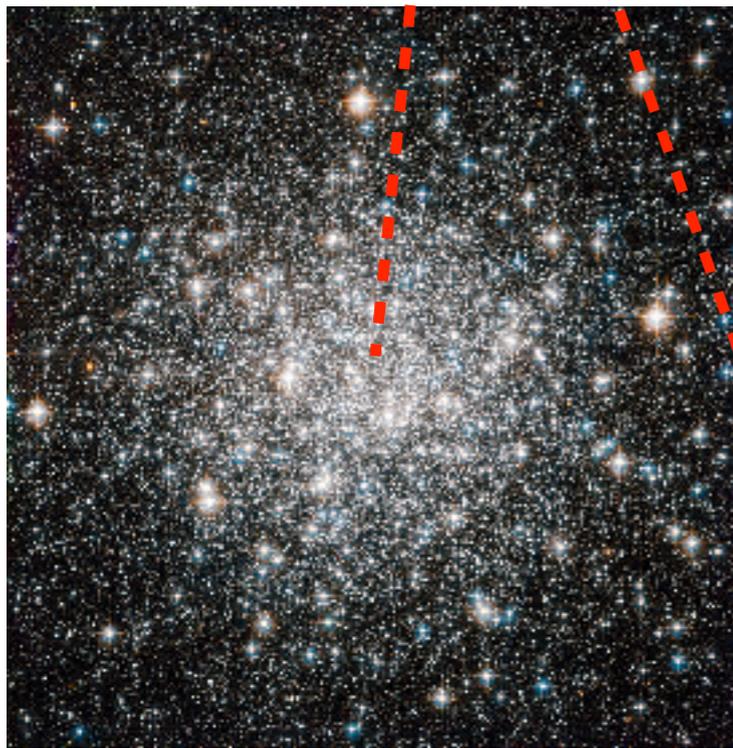

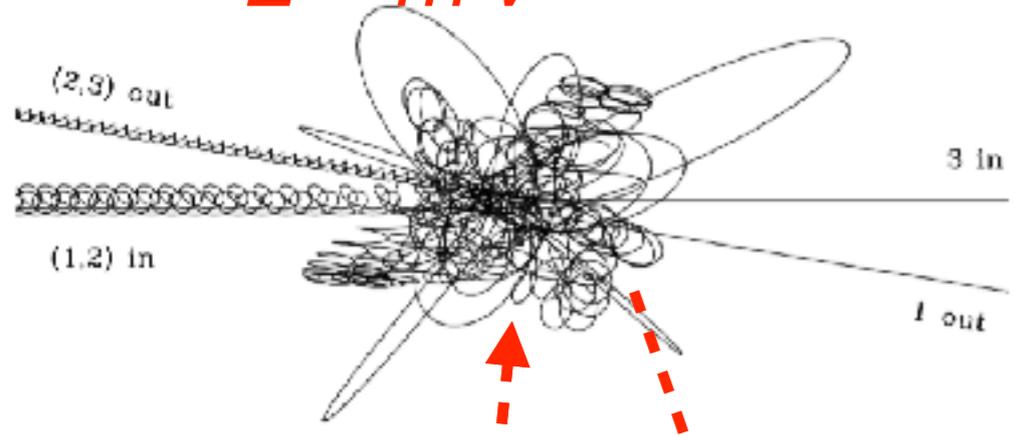

50% of massive stars were born in binaries

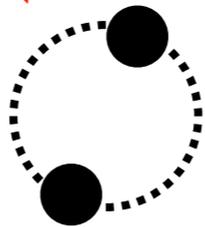

(Field binaries. e.g. Belczynski et al. 16)

Formation: Stellar Binaries

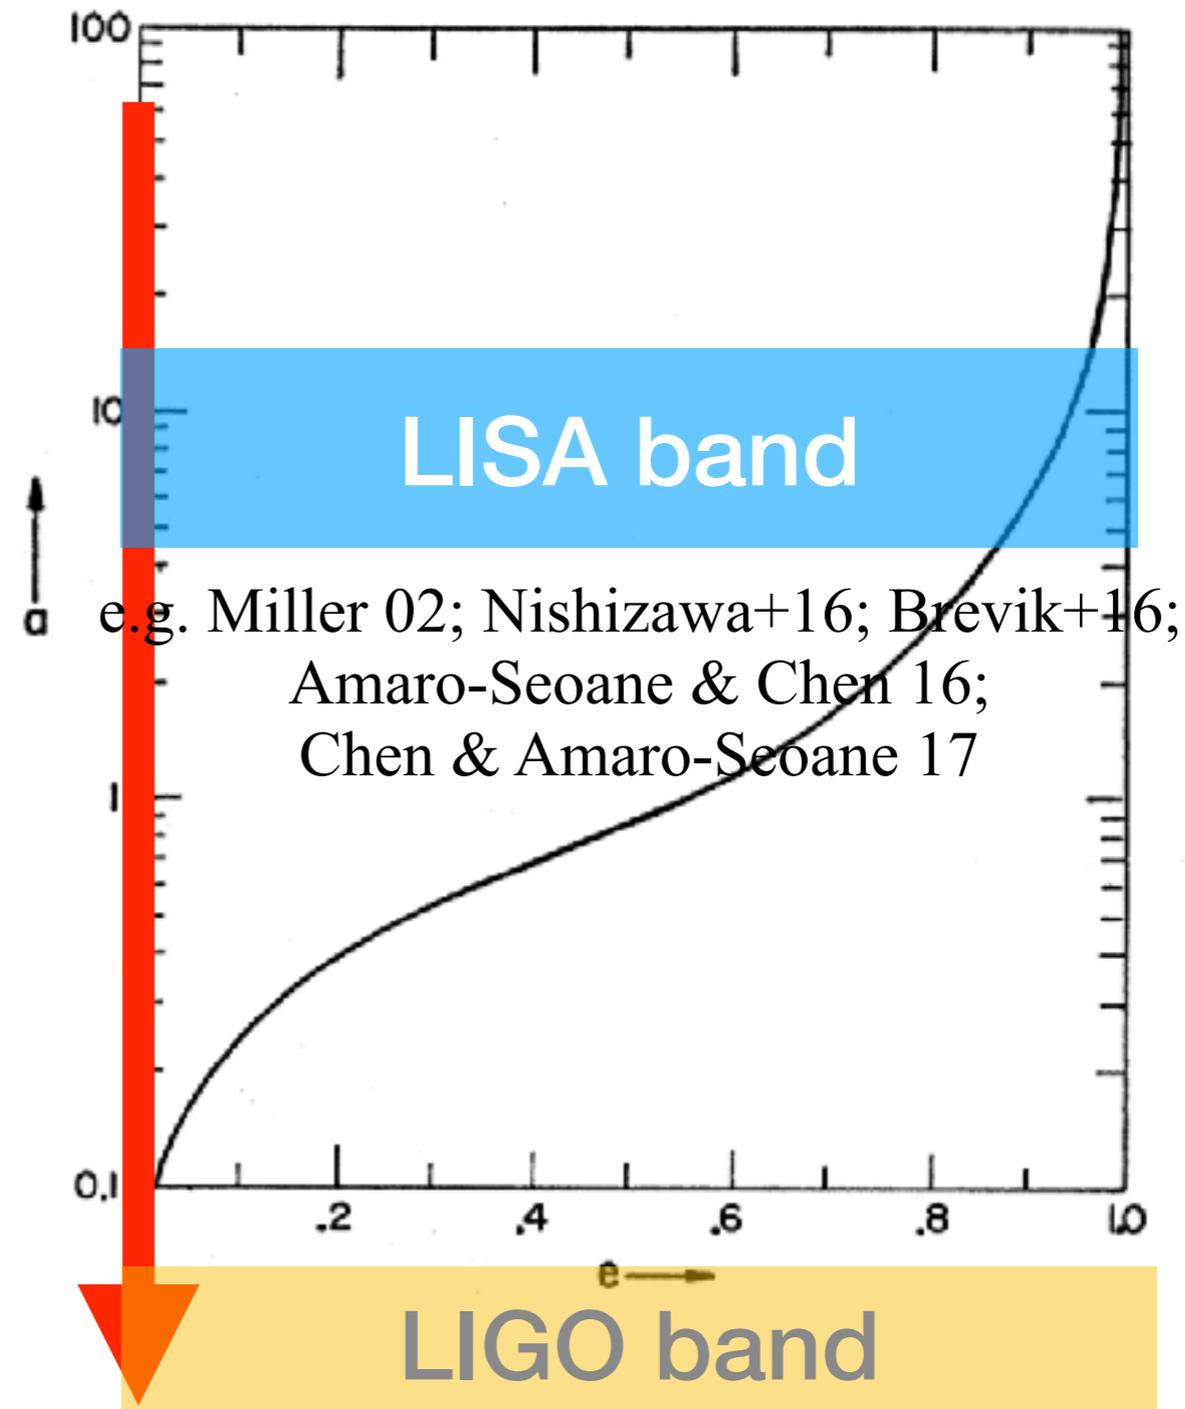

$$E \sim m v^2$$

(Dynamical binaries.
e.g. Rodriguez et al. 16)

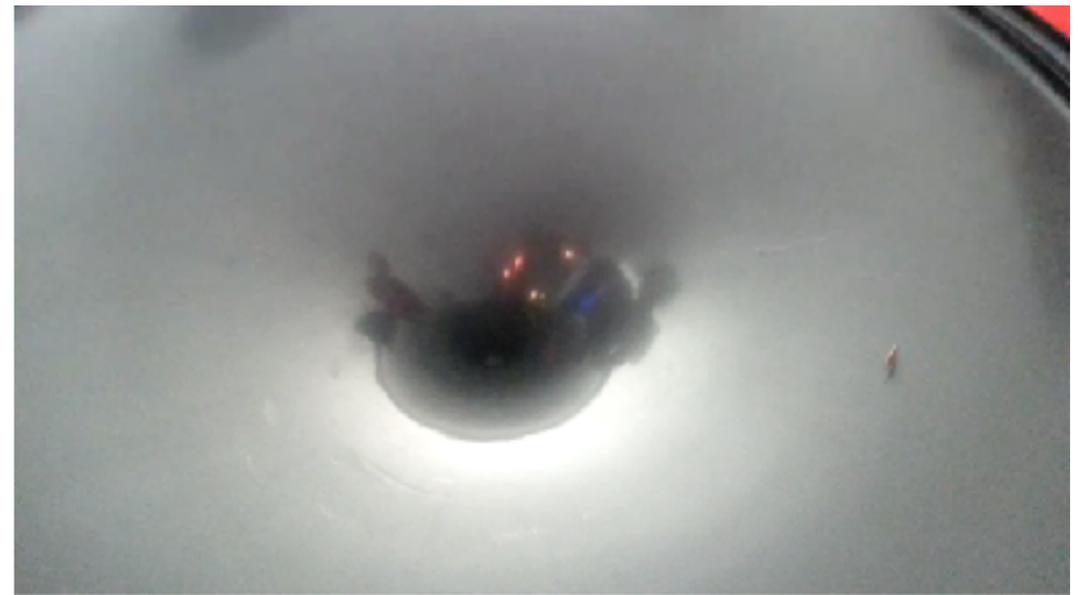

Distinguish different binaries

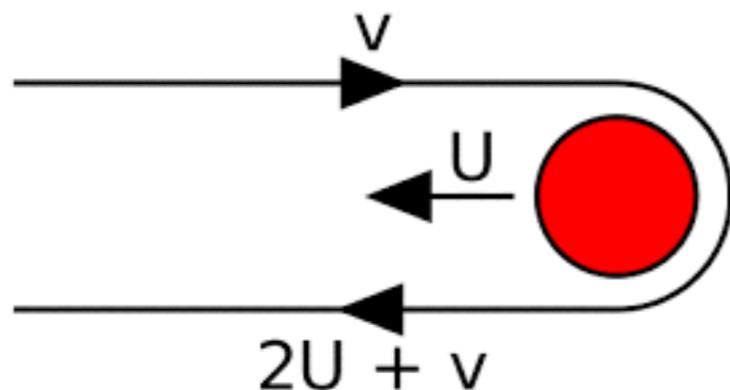

Formation: SMBH Binaries

- Scales (in km)
 - SMBH: $3e6$ km; Galaxy: $3e17$; Mean Galaxy distance: $3e19$

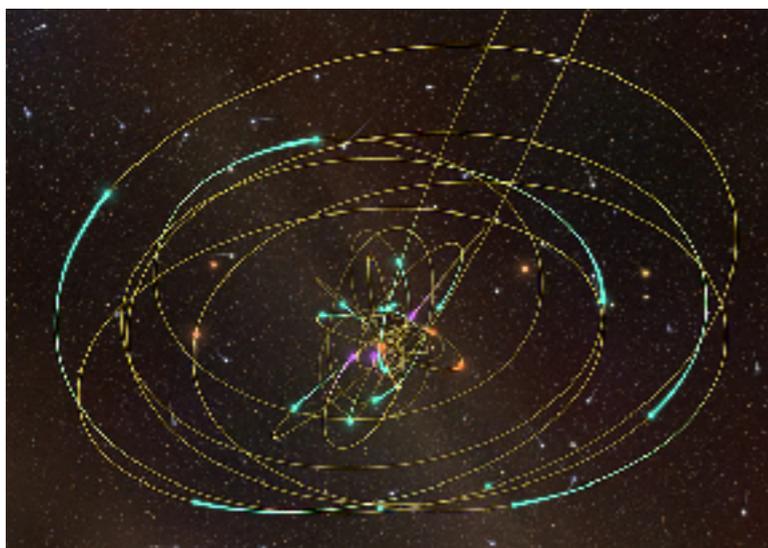

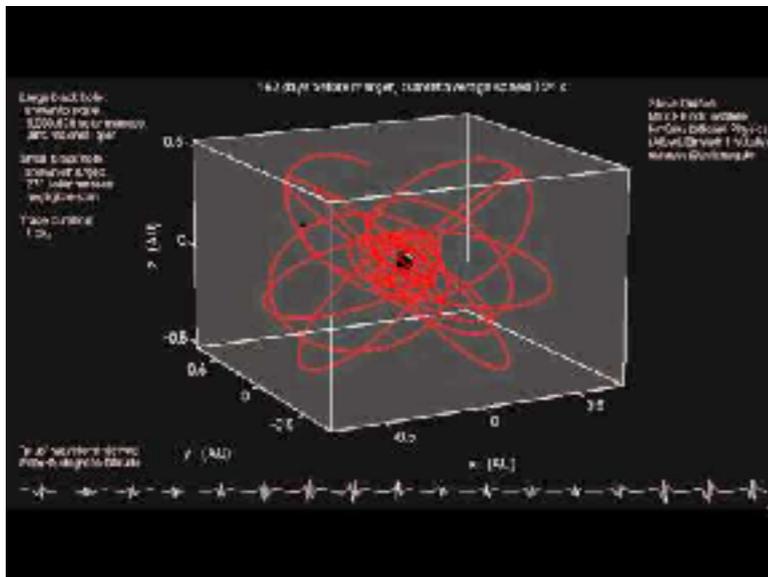

- Galaxies merge

- Dynamical friction
- The “final parsec ($3e13$ km)” problem (e.g. Begelman+1980, Merritt & Milosavljevic 05; Berczik+05,06; Chen+08,09,11)

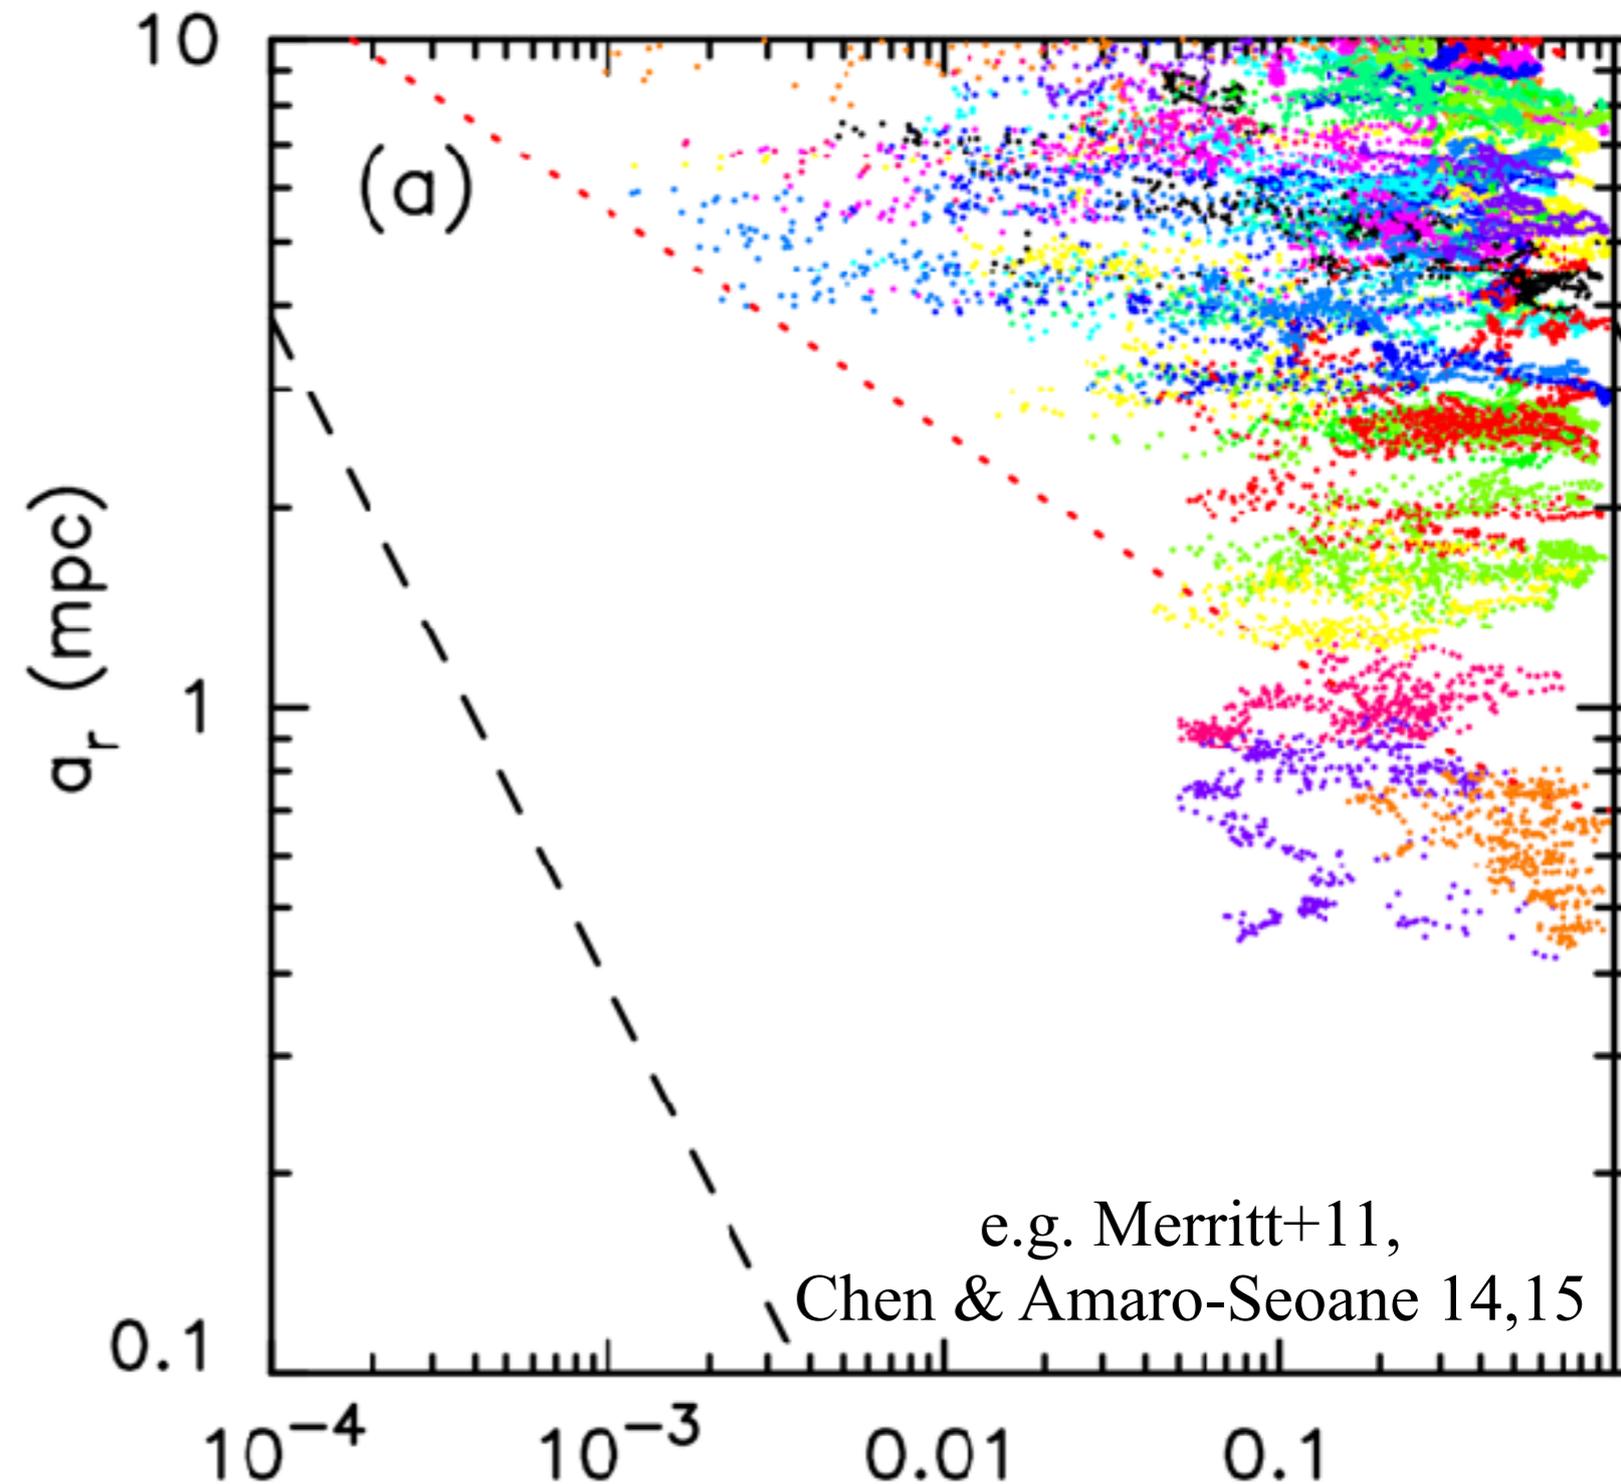

Formation: EMRIs

Credit: S. Drasco

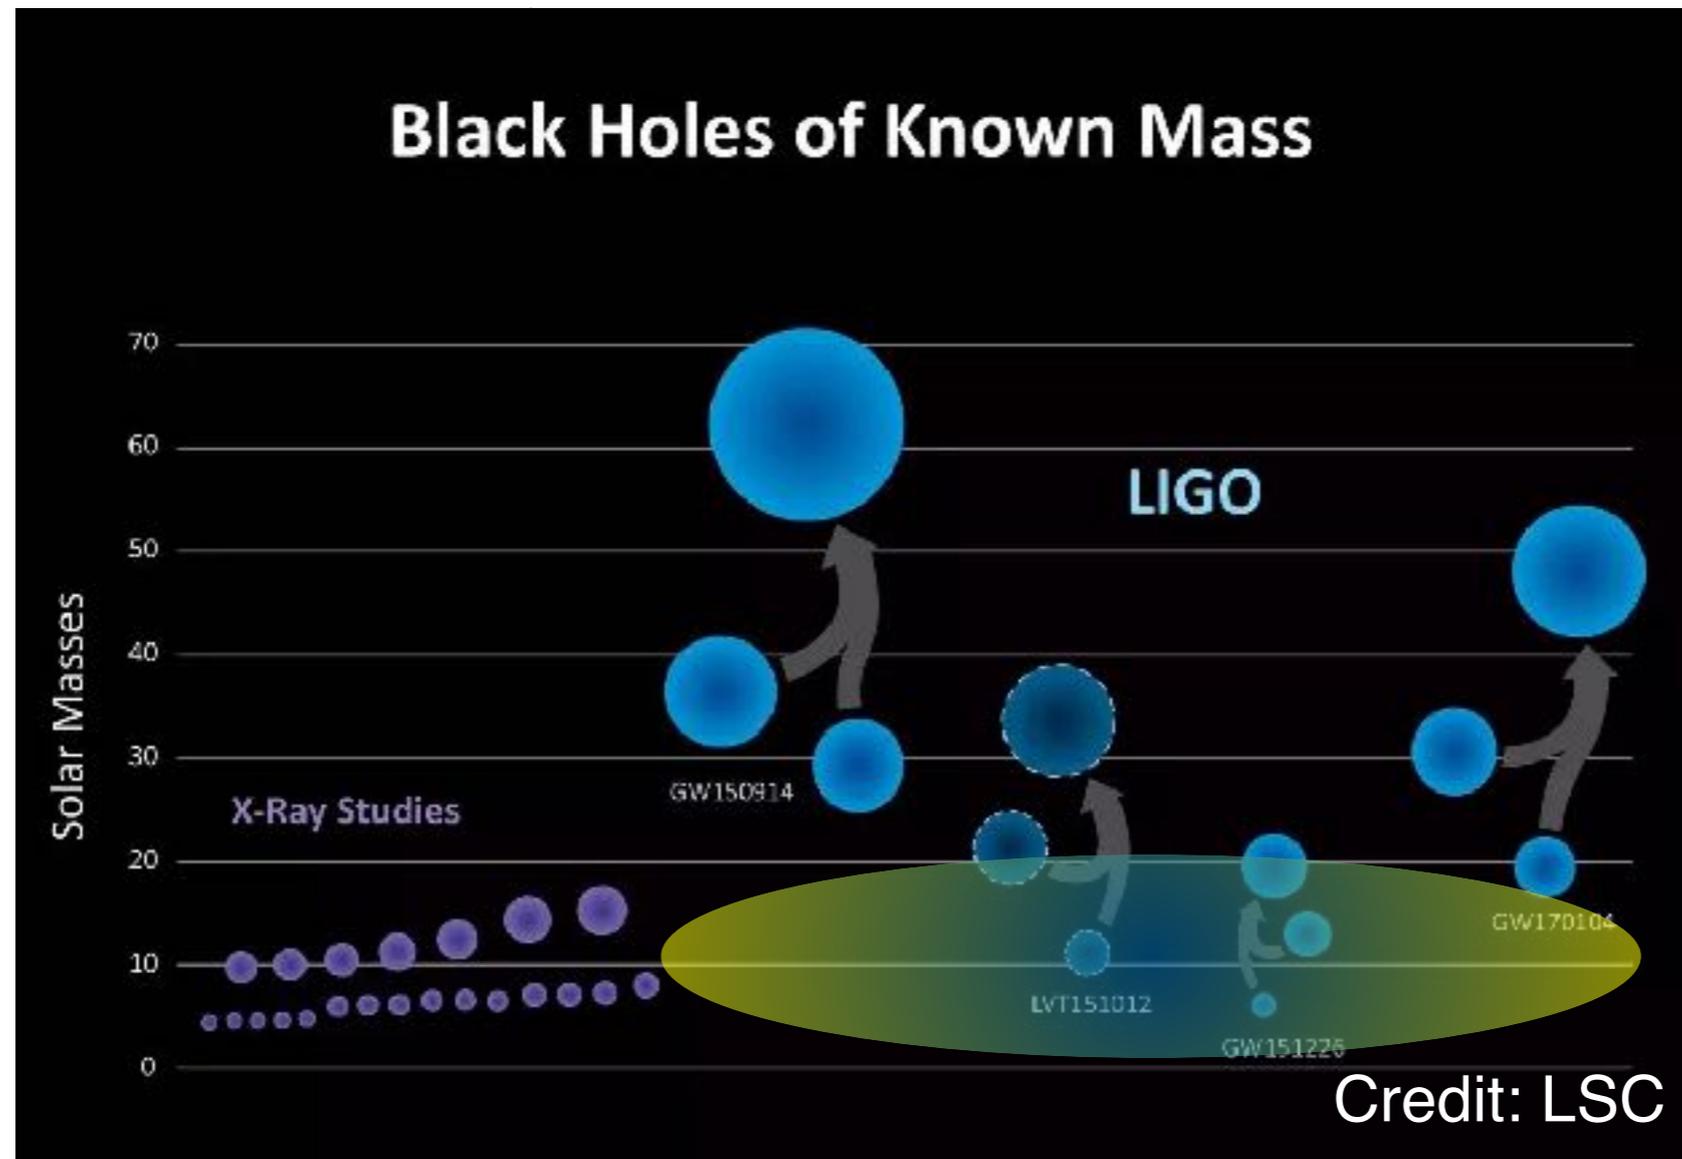

Credit: UCLA
Galactic Center Group

SMBH: $1e7$ km; SBH: 30 km

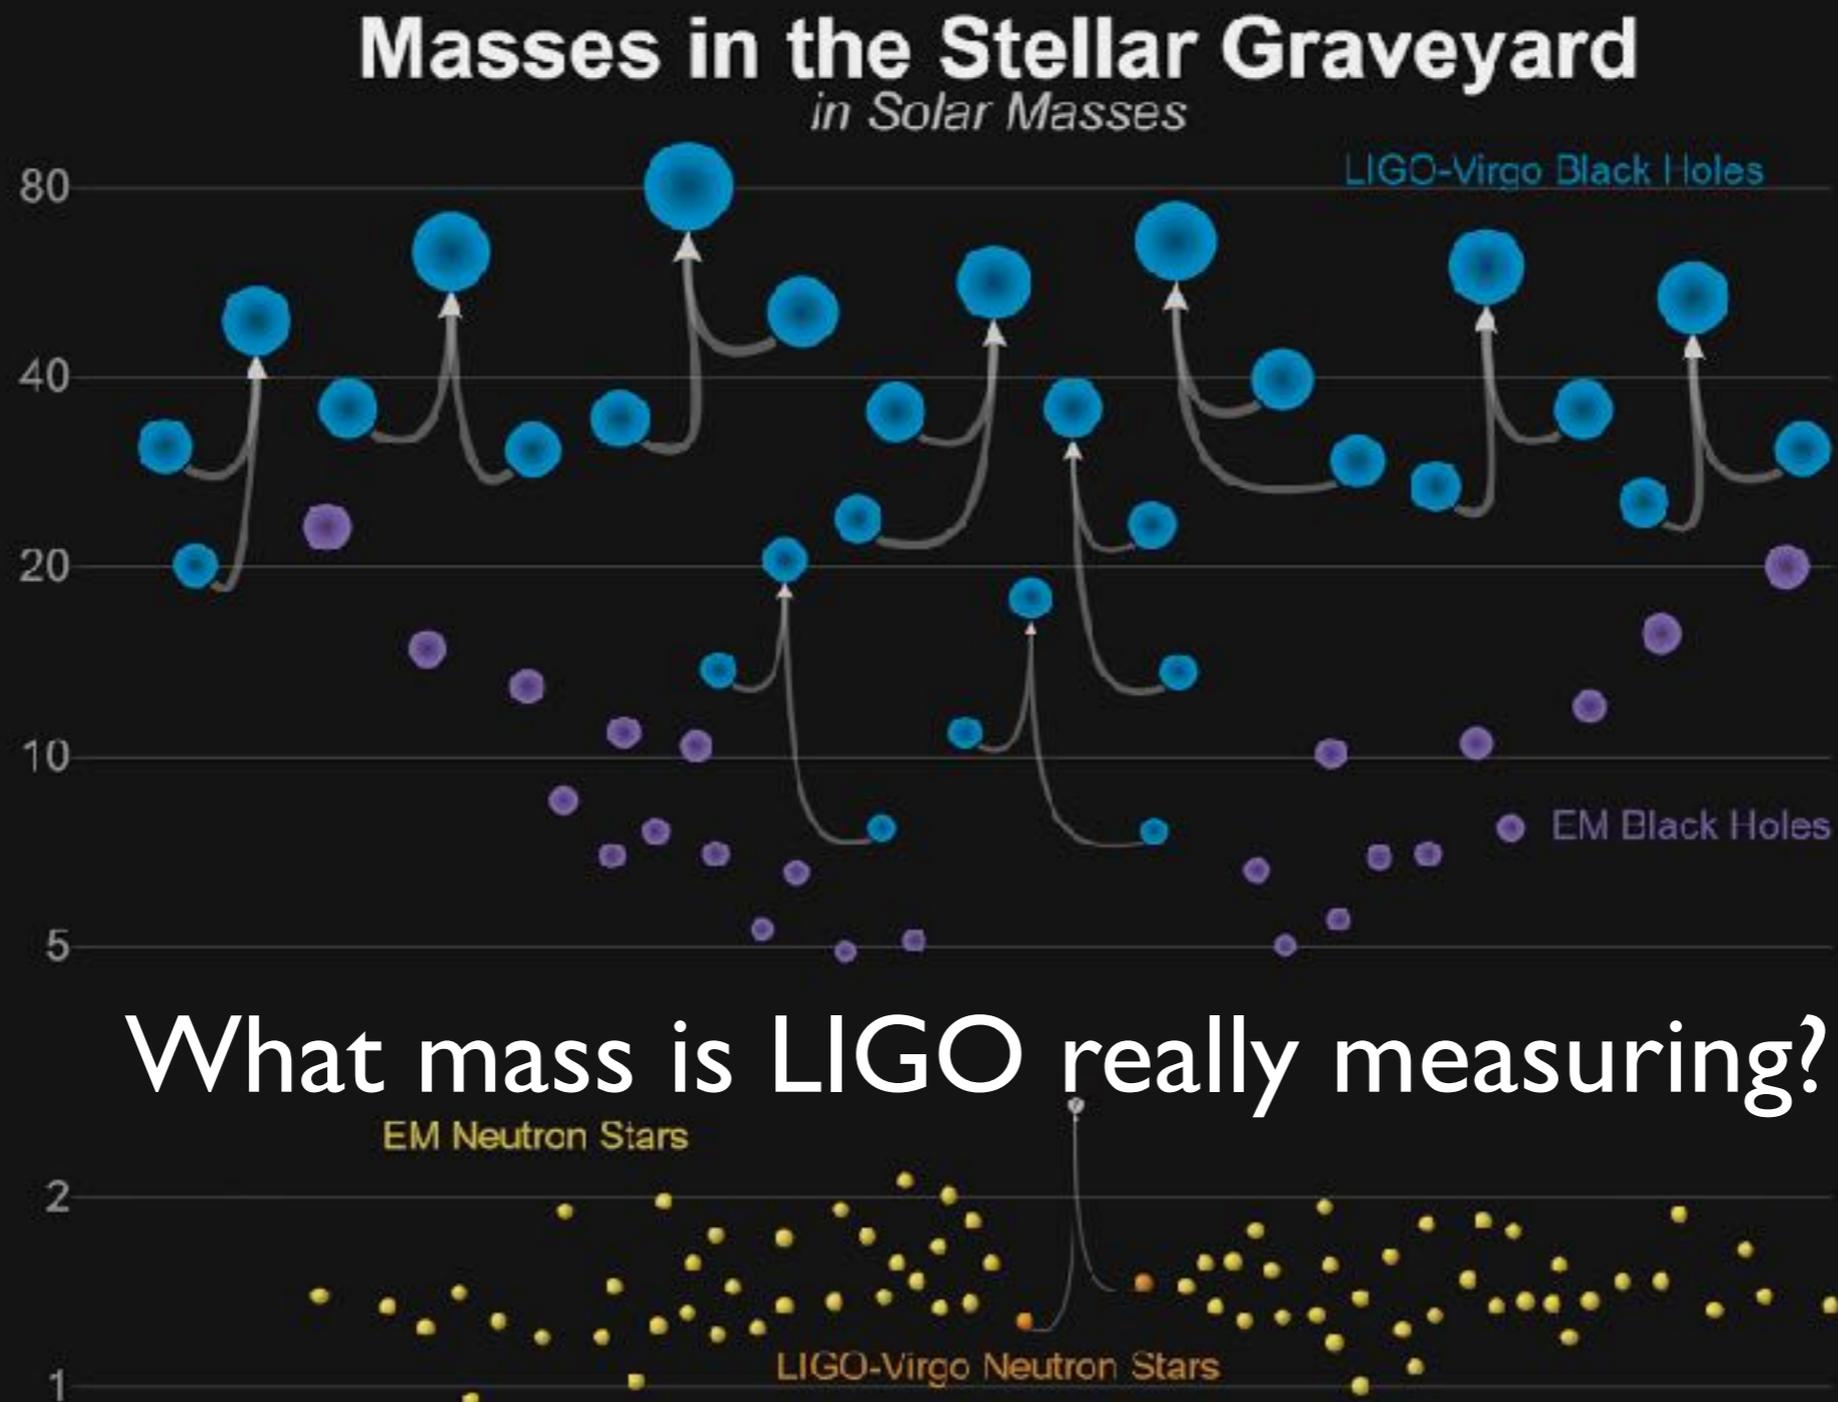

What's Next: Let's make a prediction

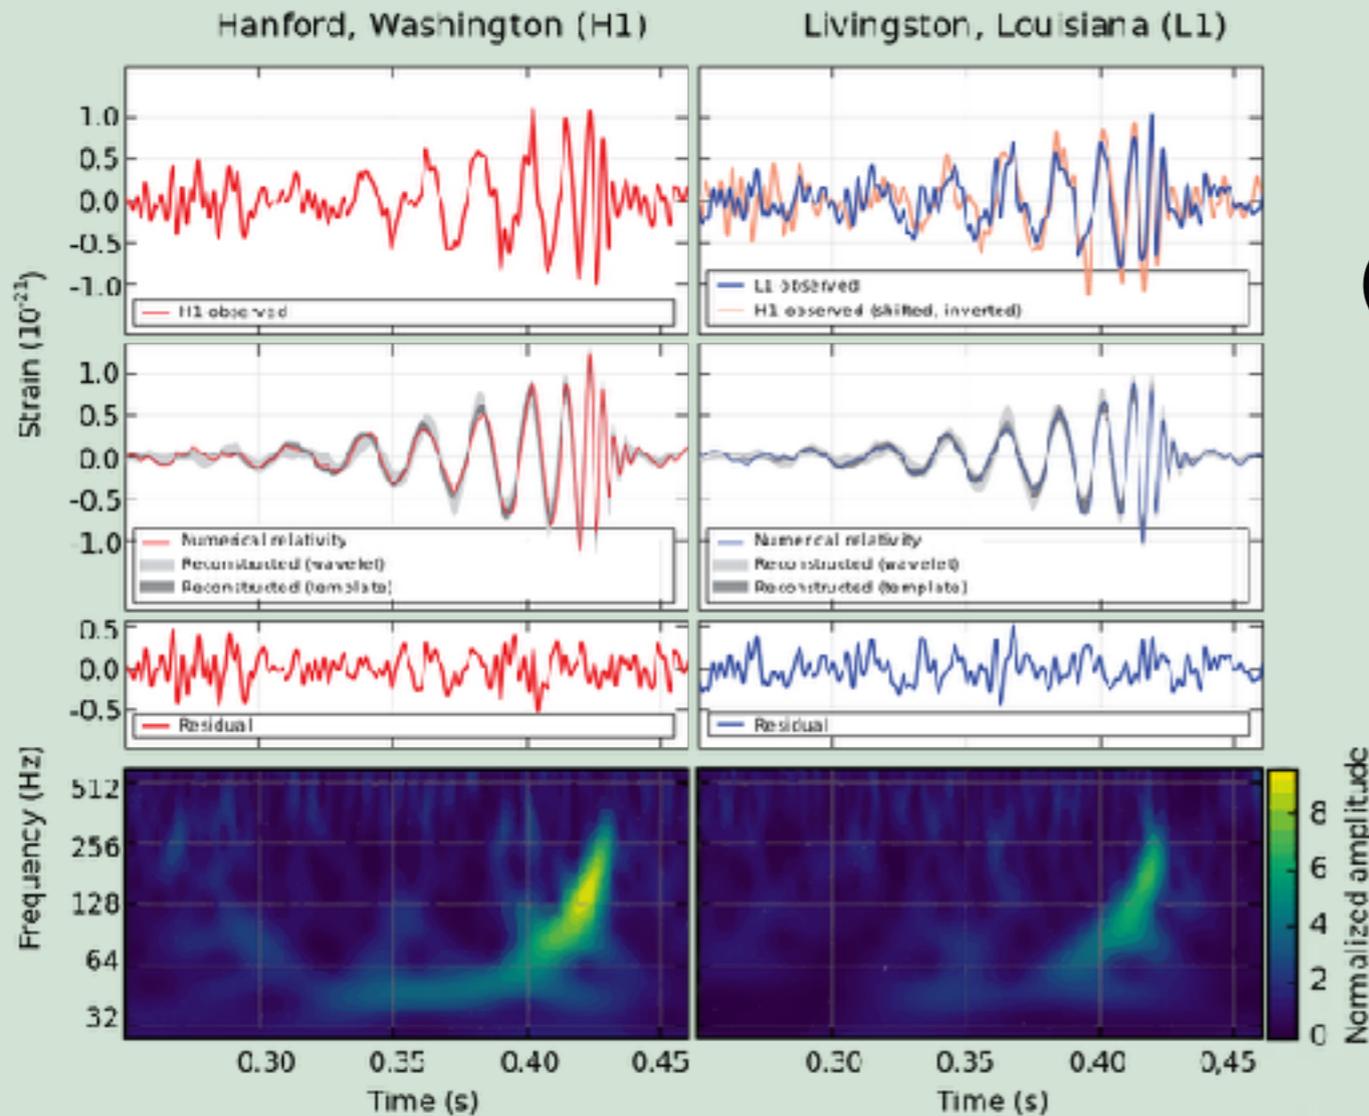

- Explanations: Low metallicity, primordial black hole, redshift (Chen+17)...

LIGO/Virgo detected GWs, but...

Measurement

Observables: the chirp
(Abbott et al. 2016, THE paper)

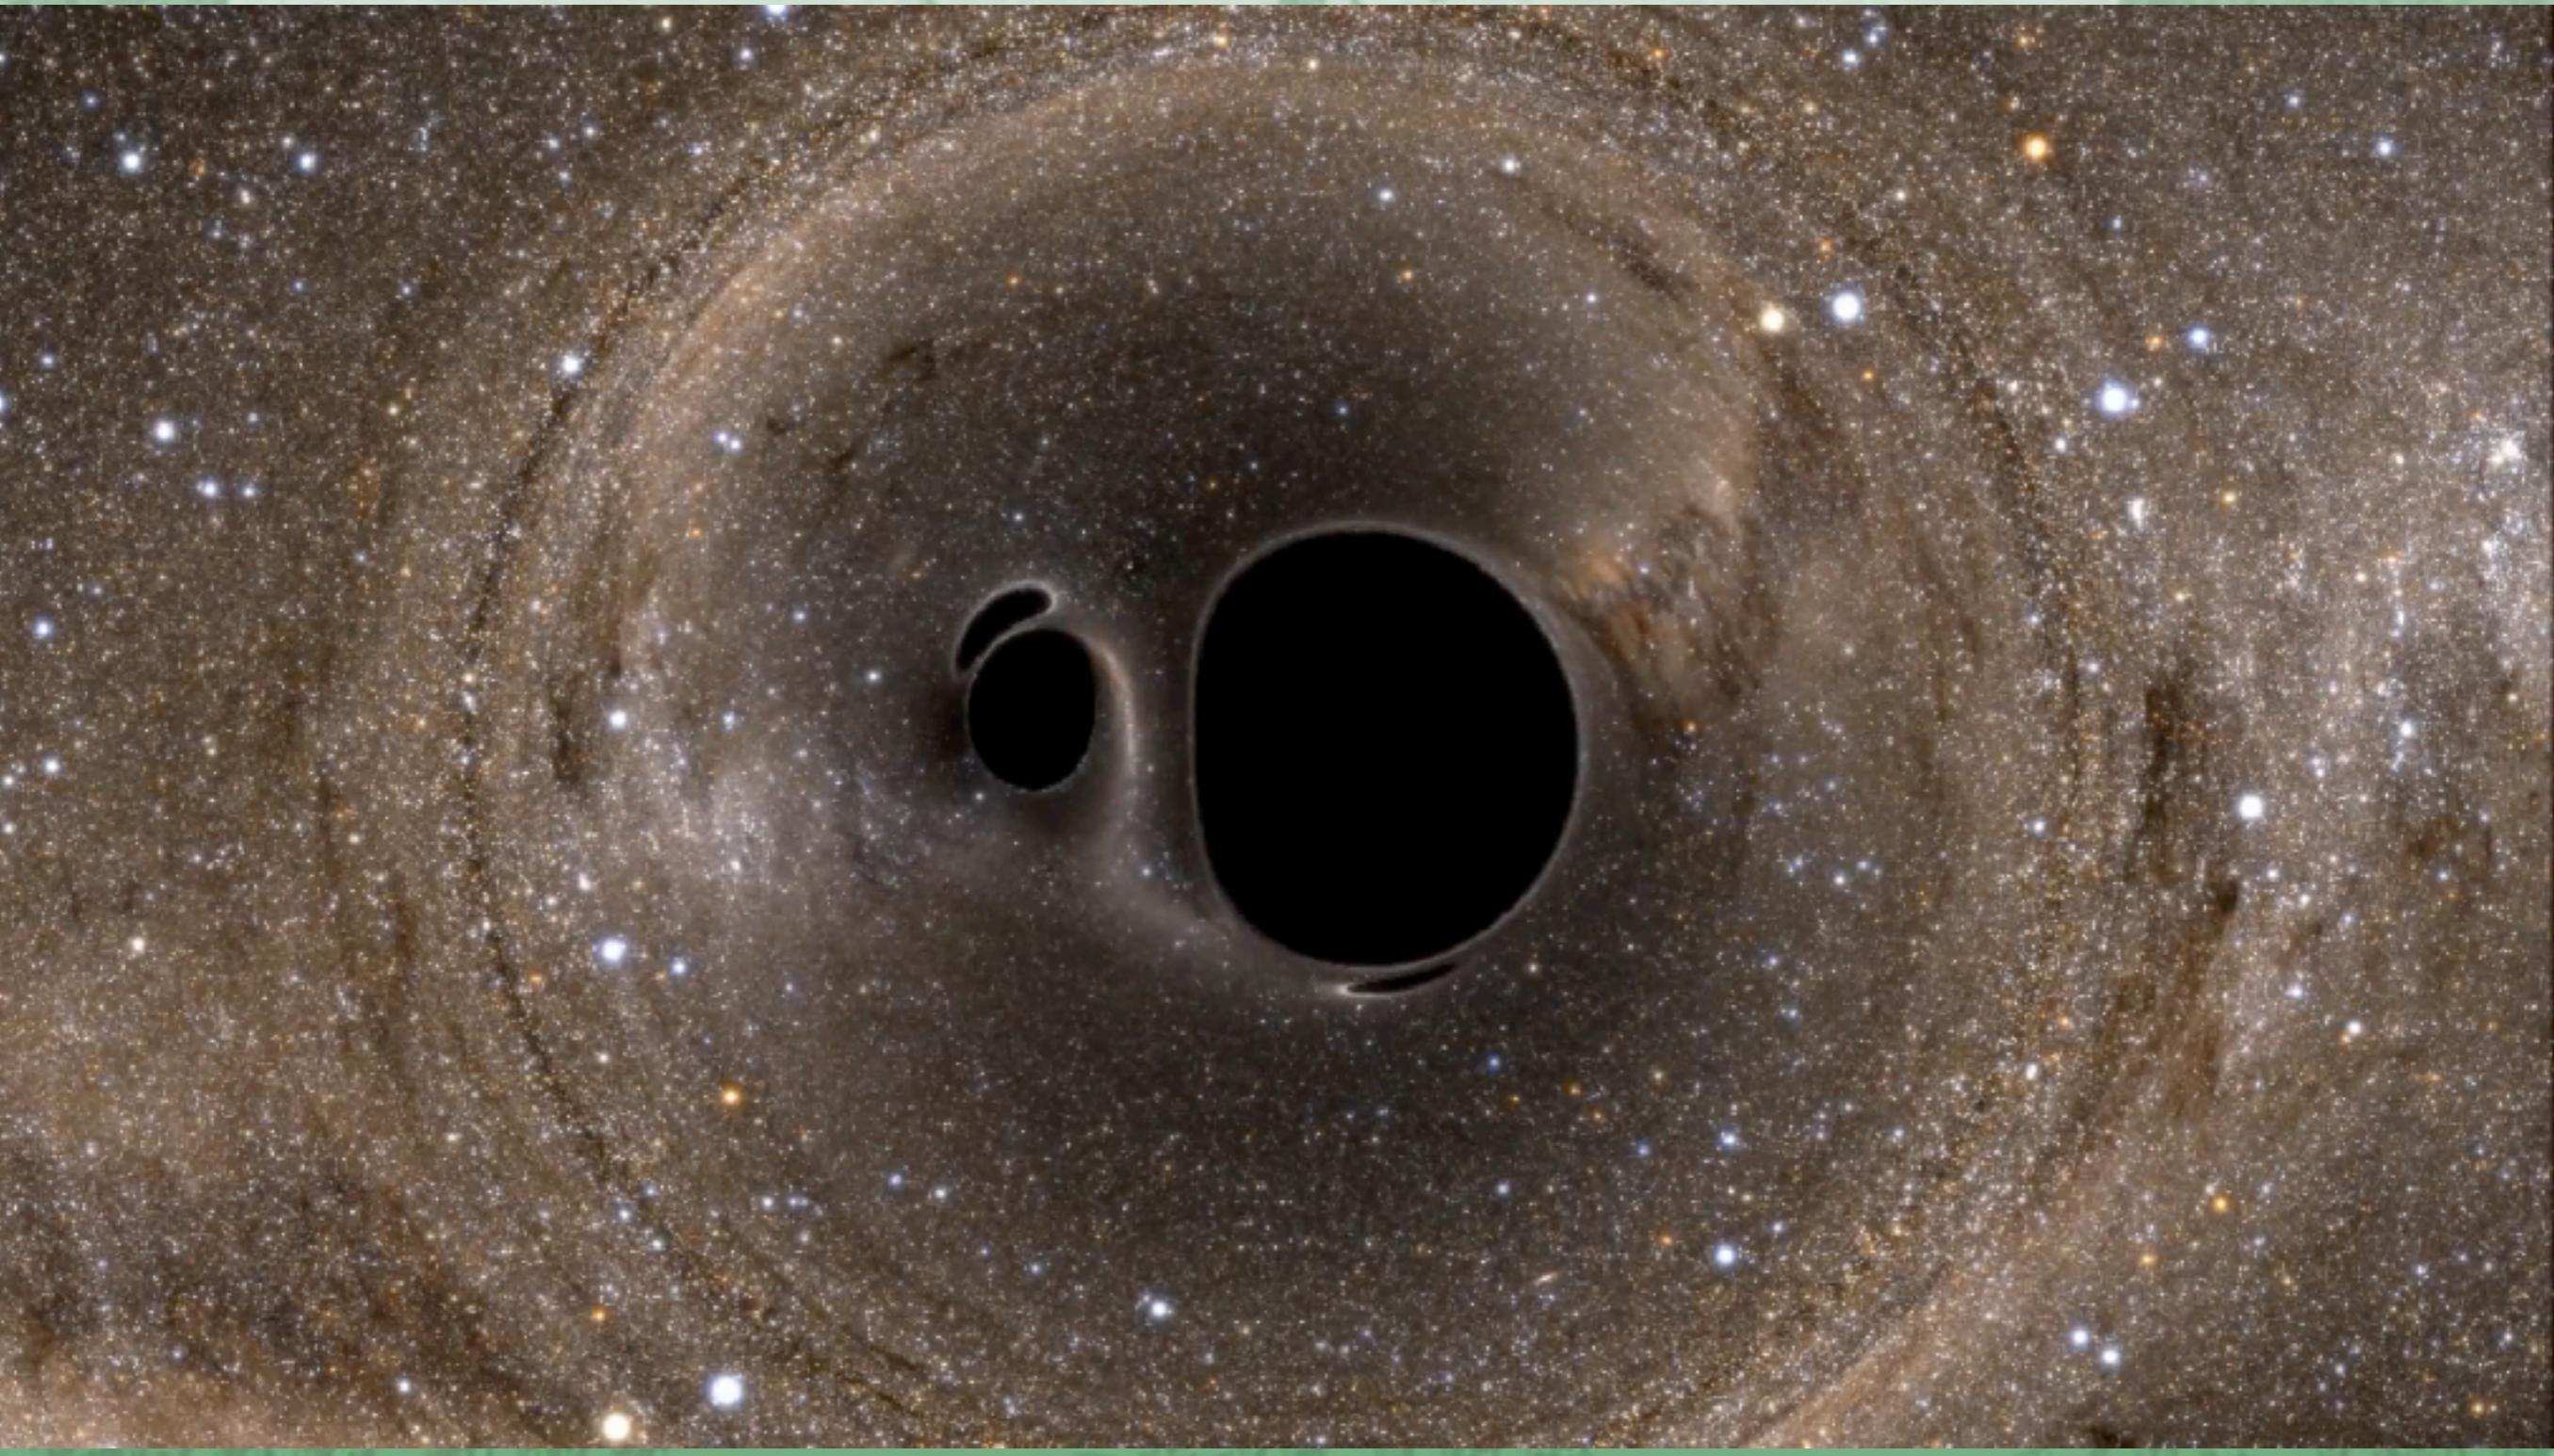

- $h(m_1, m_2, a)$
- $f(m_1, m_2, a)$
- $df/dt(m_1, m_2, a)$

$$\mathcal{M} := \left(\frac{5f^{-11/3} \dot{f}}{96\pi^{8/3}} \right)^{3/5} = \frac{(m_1 m_2)^{3/5}}{(m_1 + m_2)^{1/5}}$$

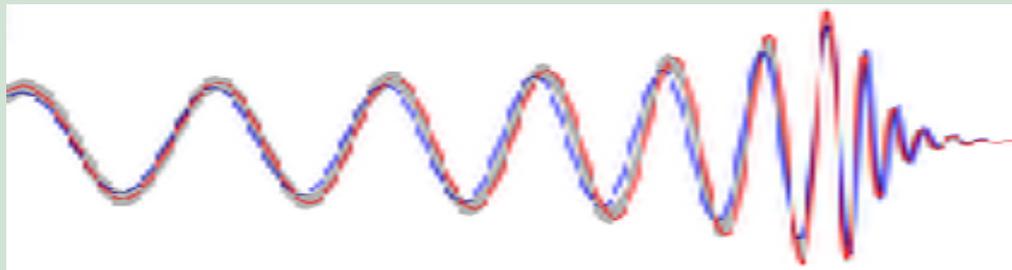

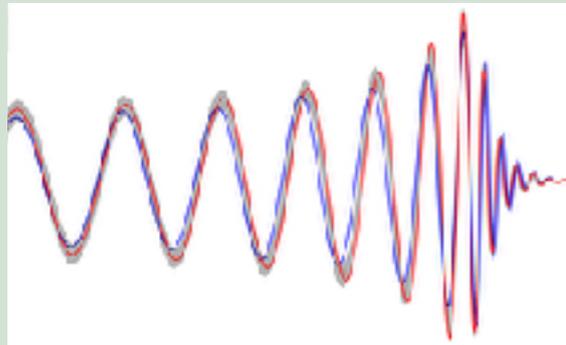

$$d = (4\mathcal{M}/h) (\pi f \mathcal{M})^{2/3}$$

The sound of black hole collision

Mass-redshift degeneracy

- All types of redshift:

$$f_o = f(1+z)^{-1}$$

$$\dot{f}_o = \dot{f}(1+z)^{-2}$$

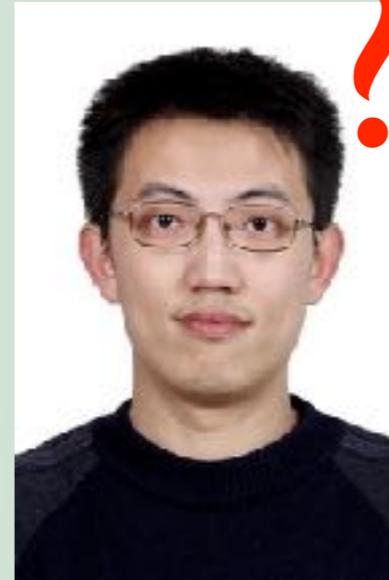

$$\mathcal{M}_o := \left(\frac{5 f_o^{-11/3} \dot{f}_o}{96 \pi^{8/3}} \right)^{3/5} = \mathcal{M}(1+z)$$

Why haven't people considered redshifts??

■ Types of redshift:

- ∞ Cosmological
- ∞ Doppler (need a velocity close to c)
- ∞ Gravitational (have to be close to the Schwarzschild radius)

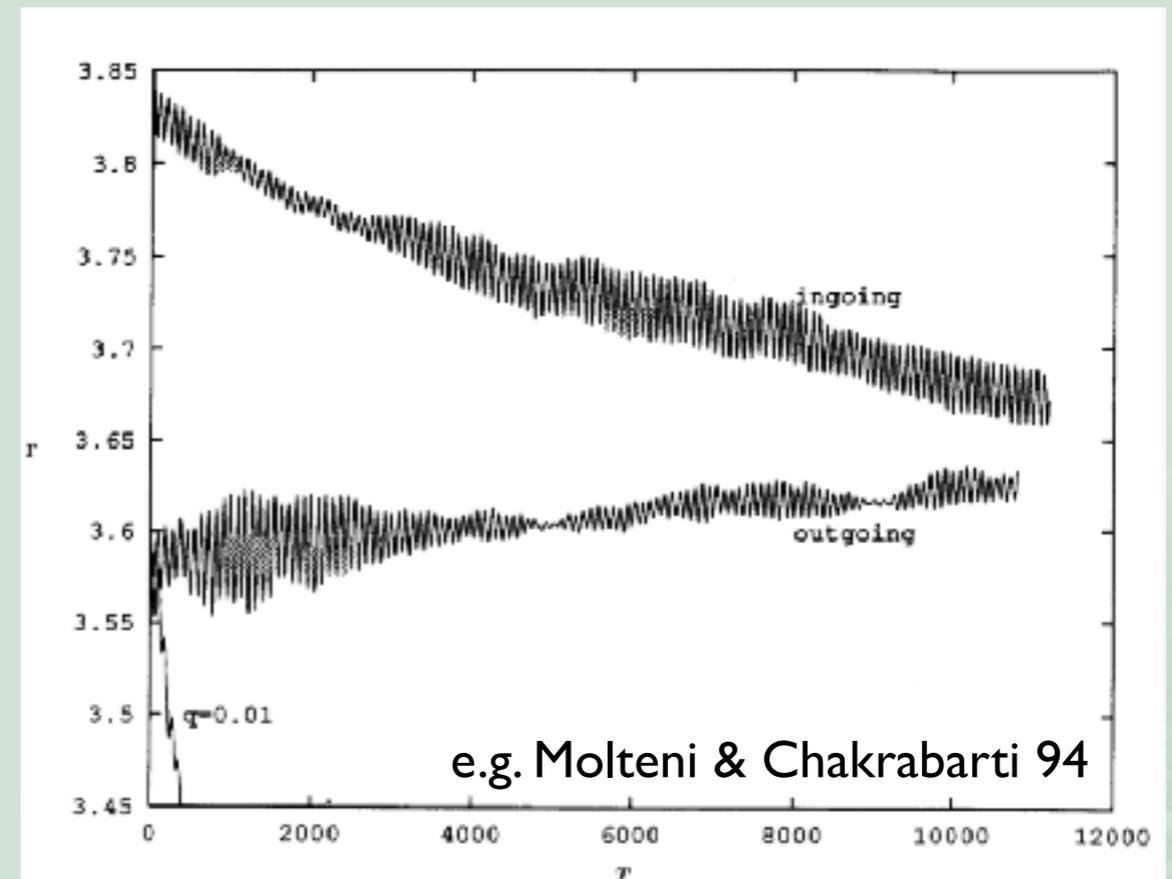

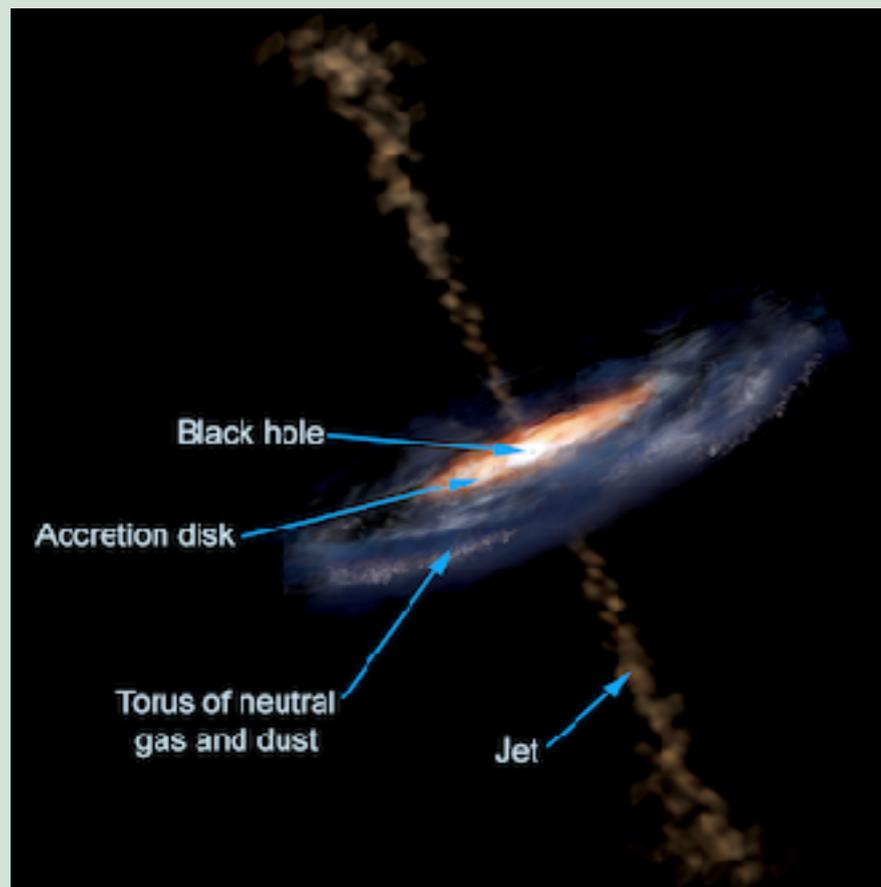

■ Formation channels:

- ∞ Conventional: Galaxy disk/bulge or globular clusters → Low velocity and shallow potential
- ∞ **Recent view:** Enhancement of mergers close to a supermassive black hole ($>10^6 M_{\text{sun}}$) because
 - ∞ Large escape velocity for compact objects
 - ∞ Mass segregation effect
 - ∞ Tidal perturbation of binaries by the supermassive black hole
 - ∞ Hydrodynamical drag if inside an active galactic nucleus (AGN)
 - ∞ See Chen, Li & Cao 2017 arXiv:1703.10543, for a brief review

Astrophysical scenarios

■ One scenario: Trapped in AGN disks:

- ∞ Star capture and growth in disk leads to BH formation (e.g. Syer 91, Goodman04)
- ∞ Event rate: $1-10^4$ per Gpc^3 per year? (Bartos+17, Stone+17, McKernan+18, Antoni+19)
- ∞ Trapping radius:

$$\frac{r}{R_S} \simeq 15 \dot{m}^{-2/7} \left(\frac{M_3}{10^9 M_\odot} \right)^{-4/7} \left(\frac{m}{20 M_\odot} \right)^{4/7}$$

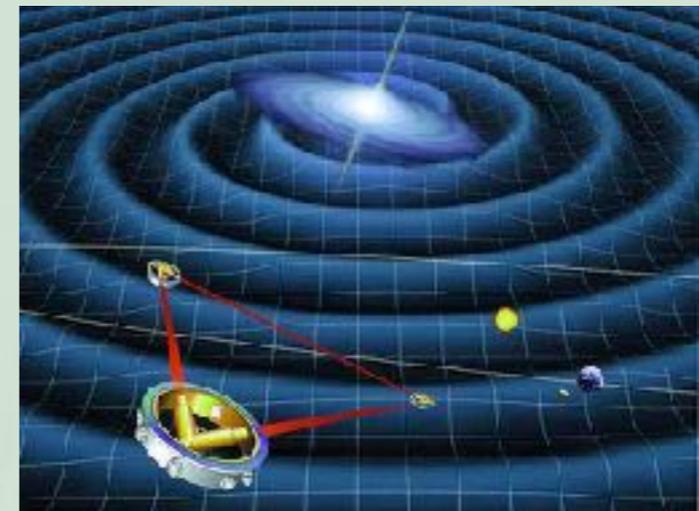

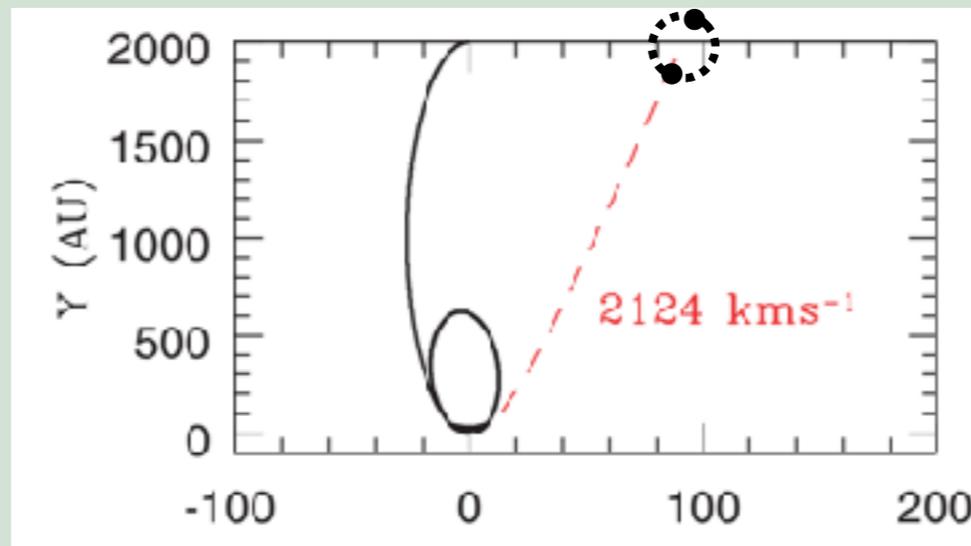

Another scenario: Tidal capture

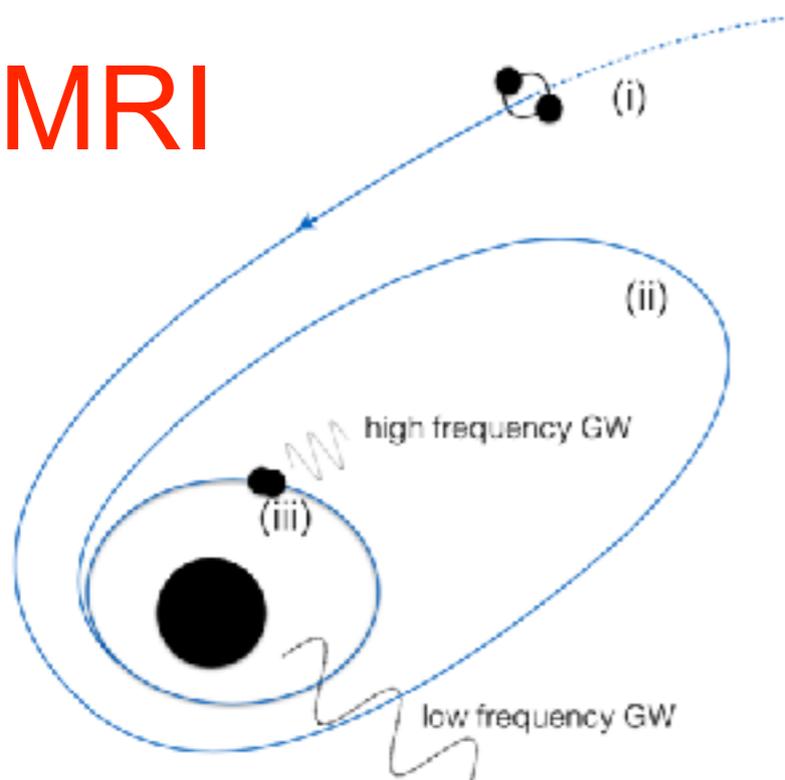

(XC & Han 2018 CommsPhy)

■ Extreme-mass-ratio inspiral (EMRI)

☞ Form at tidal radius, GW mHz, LISA/Taiji/TianQin source

b-EMRI

■ Tidal capture of BBHs:

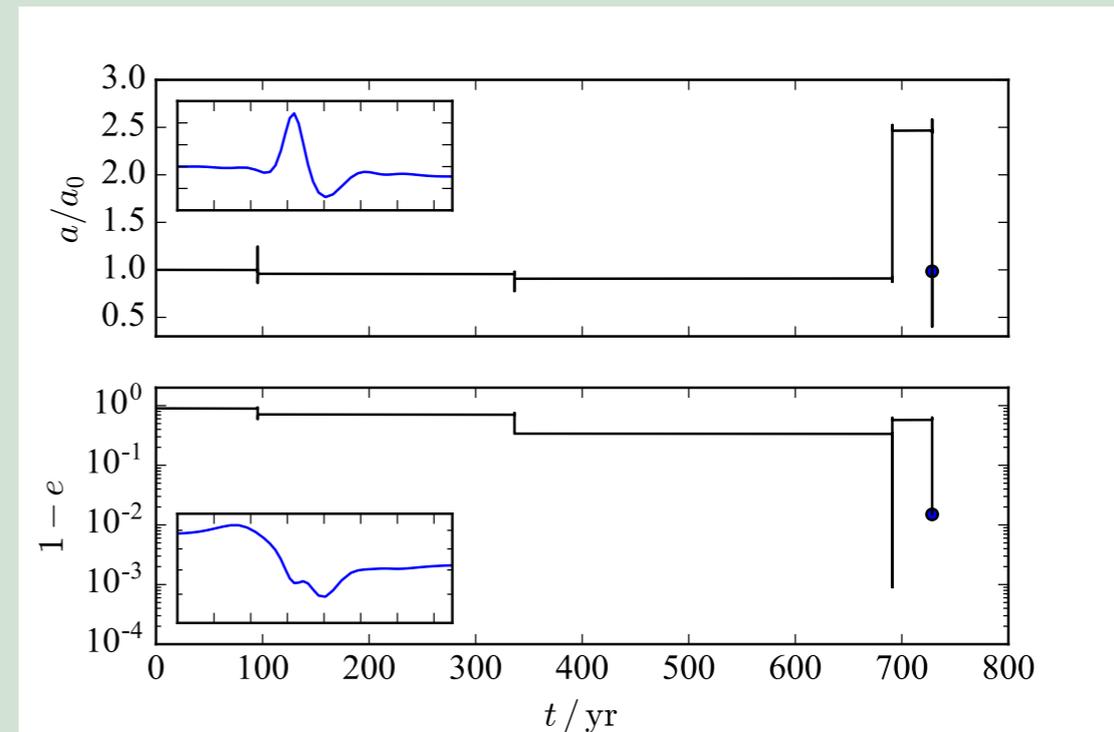

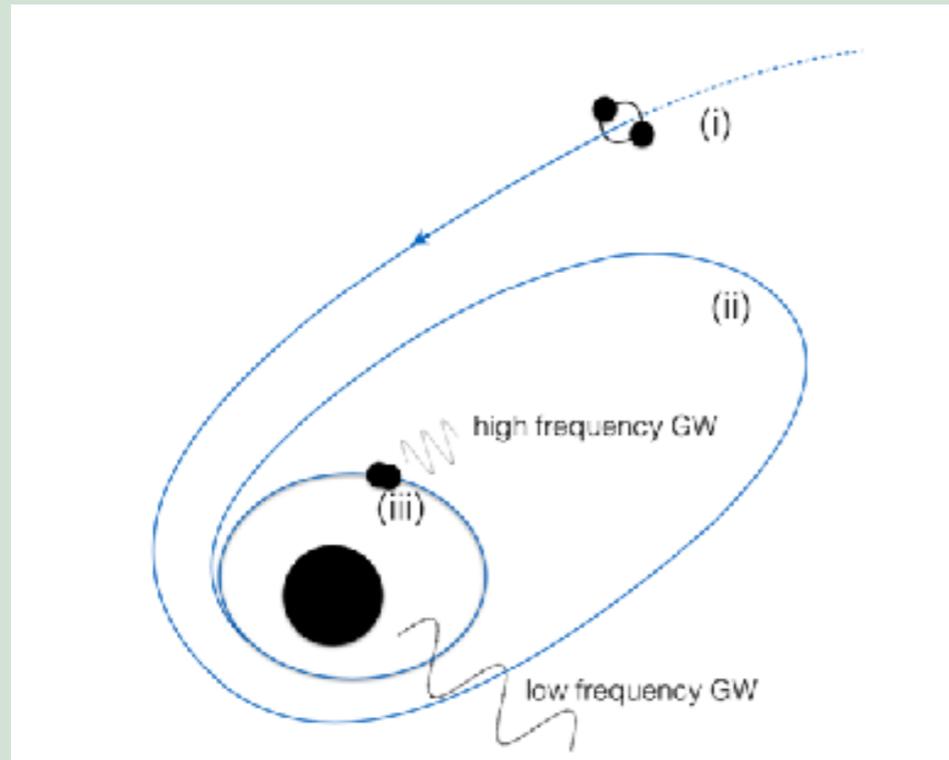

☞ according to Hills 91, Addison, Laguna, Larson 2015

$$R_p \lesssim 21 R_g \left(\frac{T_{\text{rlx}}}{10^9 \text{ yr}} \right)^{1/4} \frac{q^{3/8}}{(1+q)^{1/4}} \times \left(\frac{\eta}{0.1} \right)^{3/8} \left(\frac{m_1}{10 M_\odot} \right)^{1/2} \left(\frac{M_3}{10^6 M_\odot} \right)^{-3/4}$$

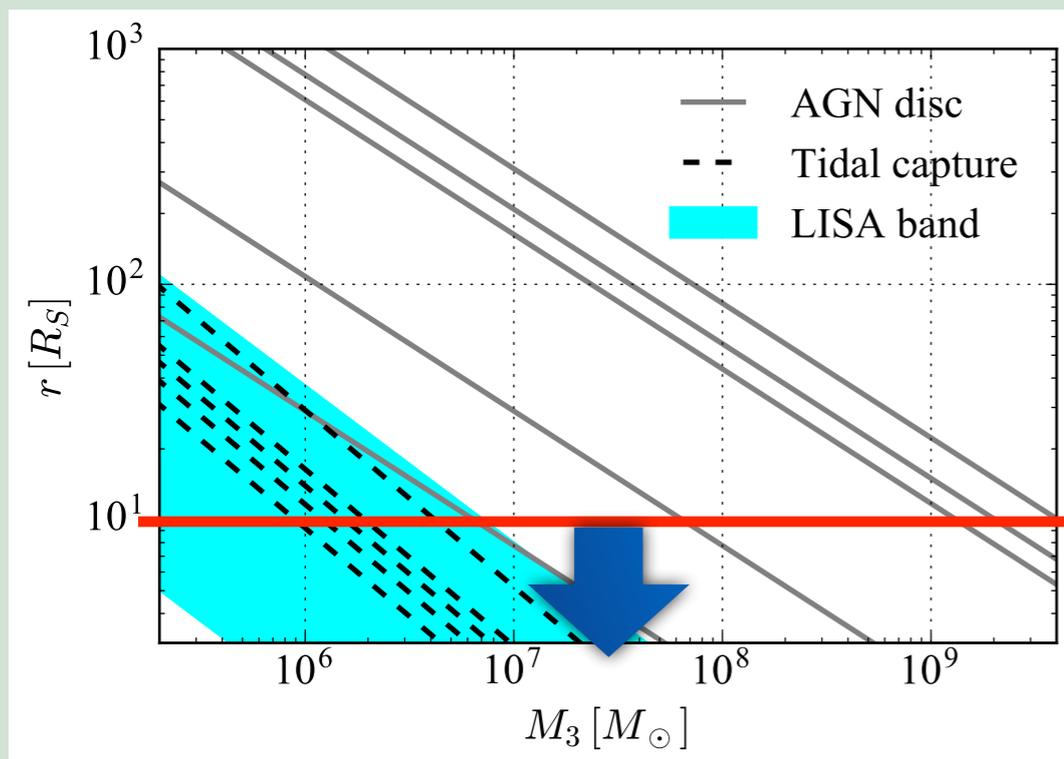

☞ Verified by our numerical scattering experiments

Long-term evolution of b-EMRIs

(XC & Han 2018 CommsPhy)

Capture radii (XC, Li & Cao, 2017)

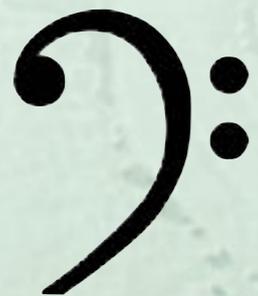

■ New features:

- ⌘ Eccentricity of the binary gets excited
- ⌘ Merger happens close to pericenter passage
- ⌘ 0.03 per Gpc³ per year unless efficient loss cone filling

Multi-band GW astronomy

New source

stronomy?

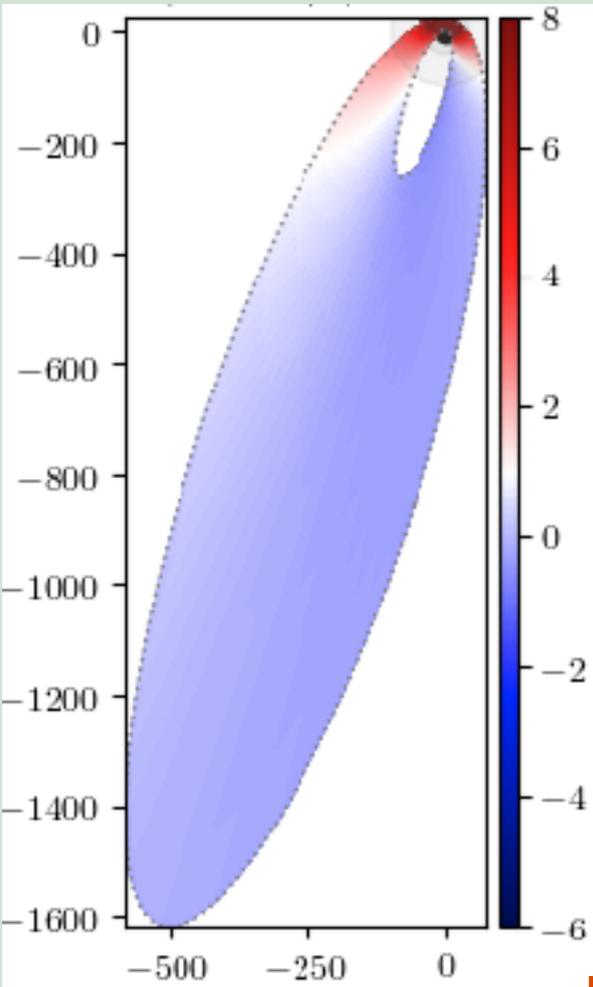

b-EMRI:b

io Inspiral

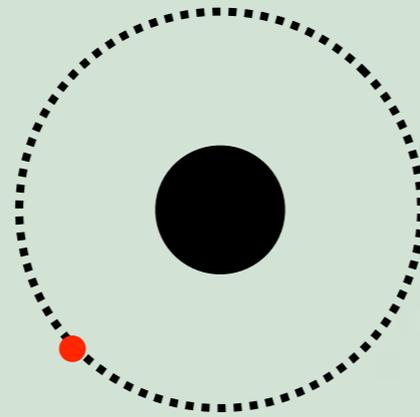

Magnitude of this effect

(Chen, Li, Cao, arXiv:1703.10543)

Redshift velocity
in unit of 10^4 km/s

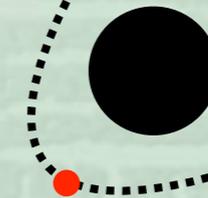

- $M_o = M(1+z_{\text{cos}})(1+z_{\text{dop}})(1+z_{\text{gra}})$
- $d_o = d_A(1+z_{\text{cos}})(1+z_{\text{dop}})(1+z_{\text{gra}})$

- Innermost stable circular orbit:

- ∞ 3 Schwarzschild radii
- ∞ $v \sim 0.408c$
- ∞ $1+z$ in total: 1.89

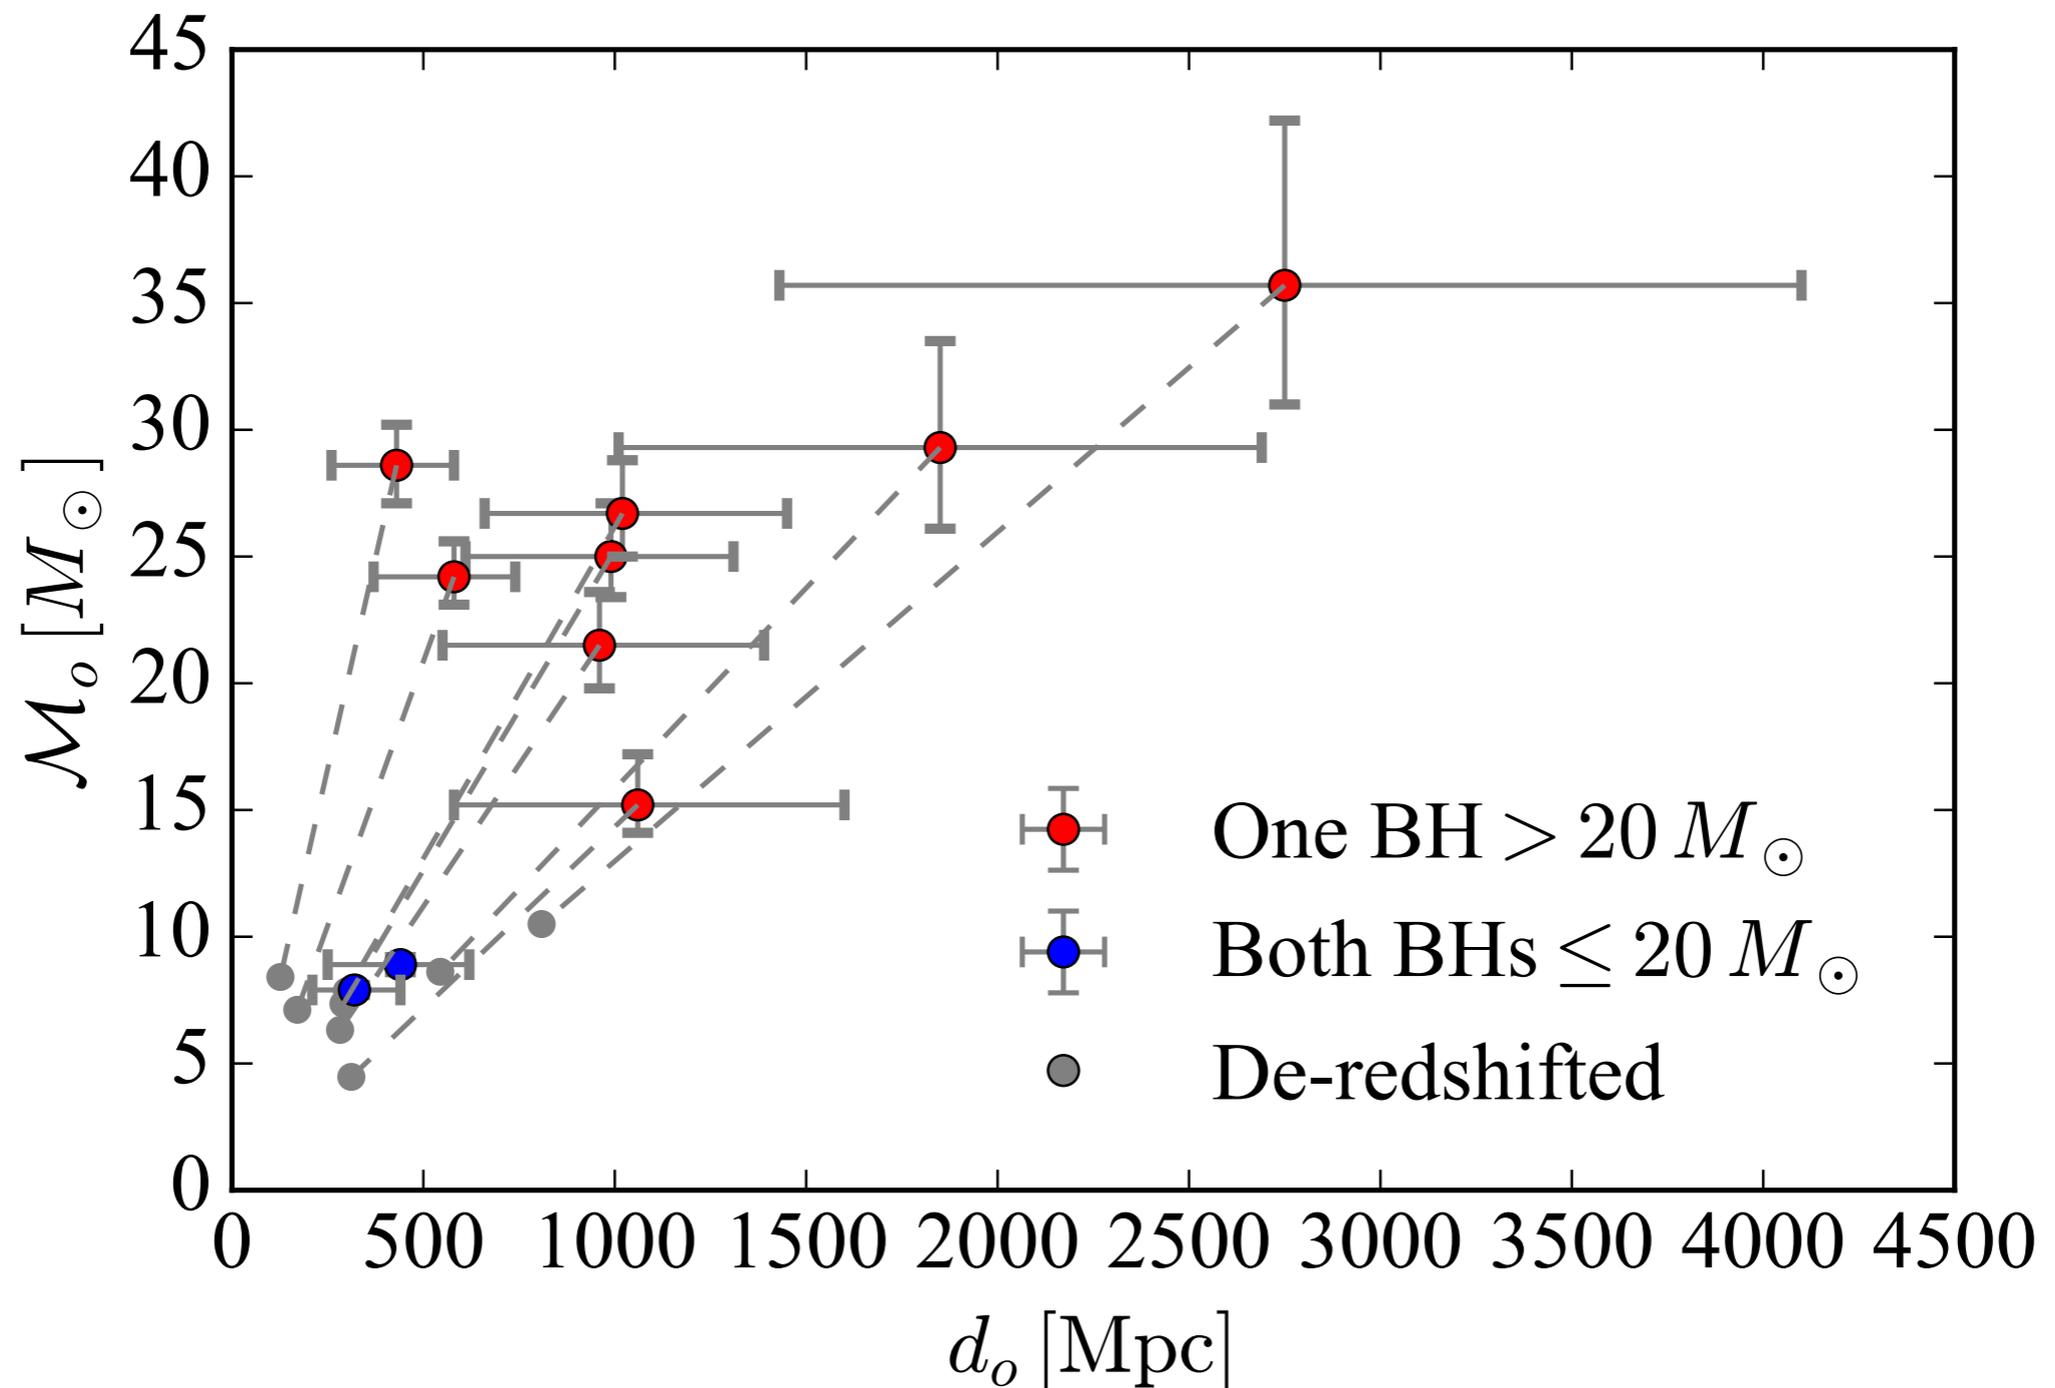

- Innermost bound orbit:

- ∞ 2 Schwarzschild radii
- ∞ $v \sim 0.707c$
- ∞ $1+z$ in total: 3.41

Compare with observations

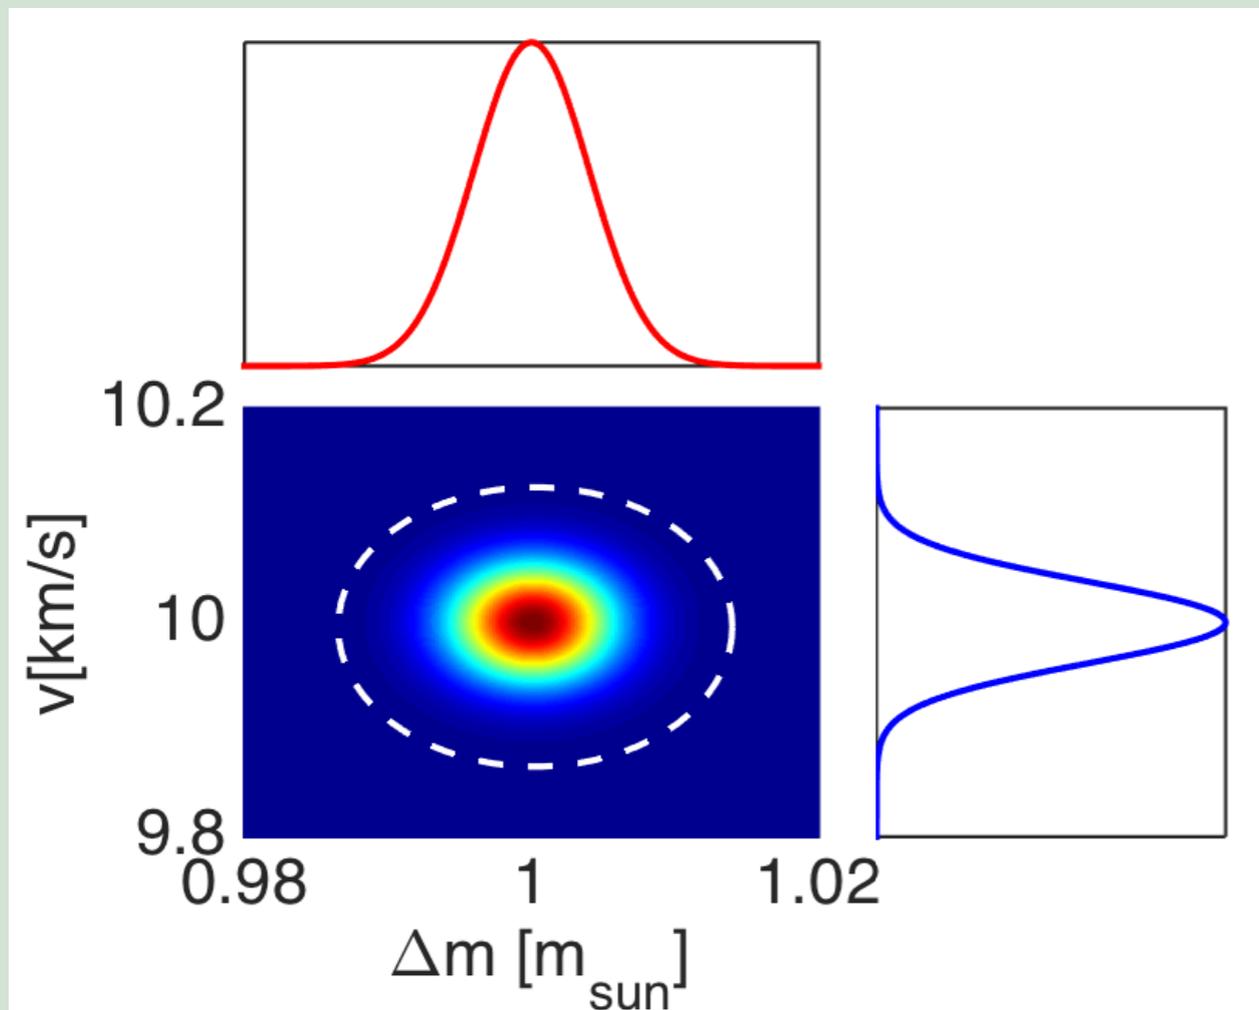

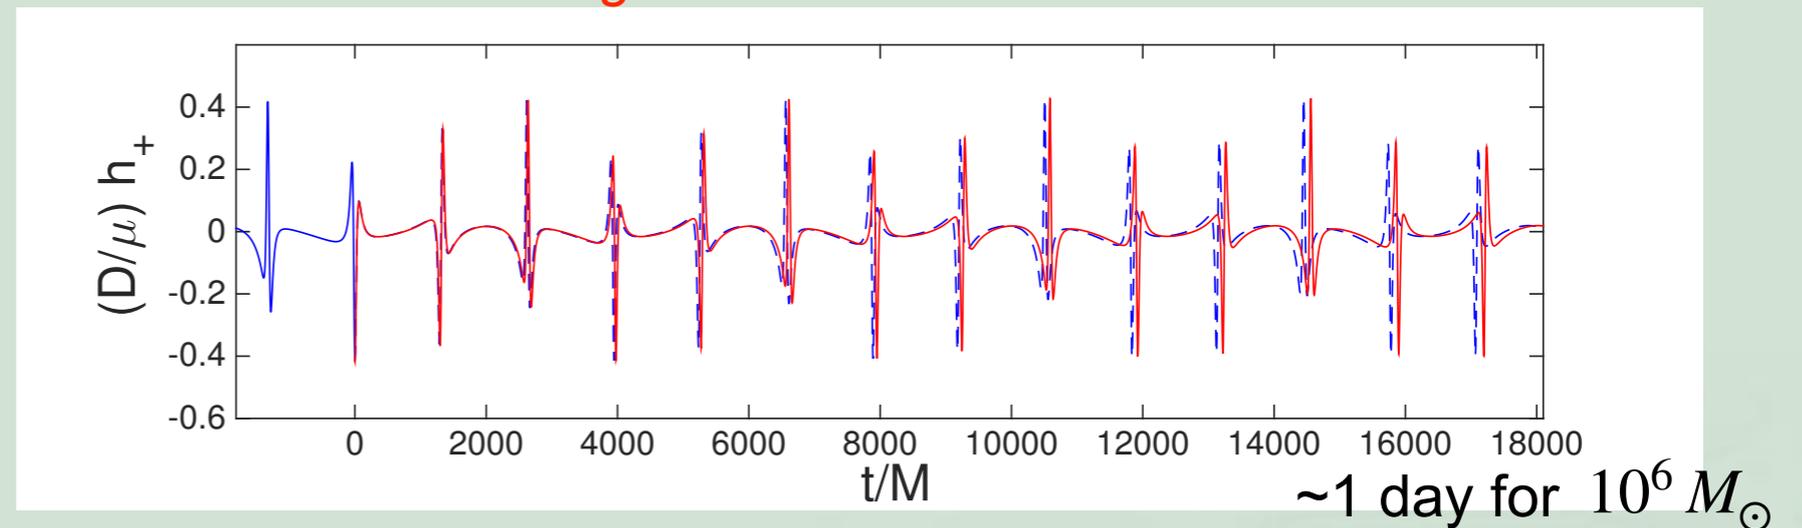

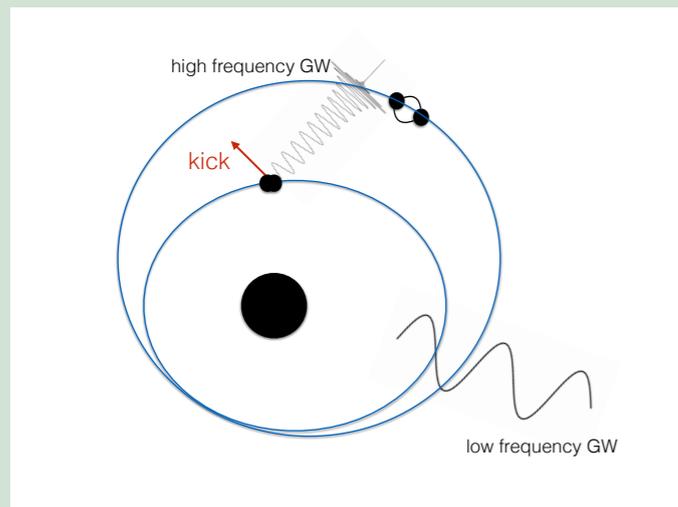

- $M_o = M(1+z_{\text{cos}})(1+z_{\text{dop}})(1+z_{\text{gra}})$
- $d_o = d_A(1+z_{\text{cos}})(1+z_{\text{dop}})(1+z_{\text{gra}})$

Why important?

(Han & Chen 2019, submitted)

A *glitch* in EMRI waveform

LISA waveform tells us v and δv

$$\delta v/v \approx 1\% \text{ when } v = 10 \text{ km s}^{-1}$$

For comparison (Gerosa+16):

200km/s using quasi normal mode

LISA waveform tells us Δm and δm

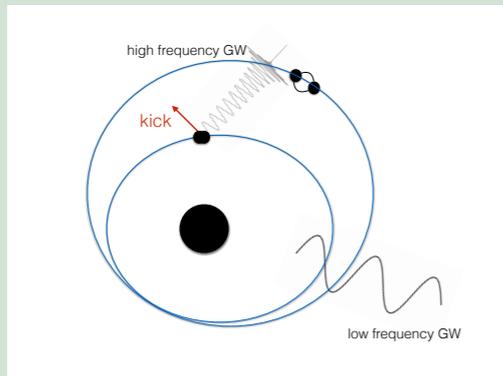

$$\delta m/\Delta m \approx 2\% \text{ when SNR} > 30 \text{ in LISA}$$

For comparison (LVC 16,17,18):

(10-30)% from LIGO/Virgo

Measure GW dispersion (Han & Chen 2019 MNRAS)

Dispersion relationship for gravitational waves:

$$\Delta t = (1 + Z) \frac{D_0}{2\lambda_g^2} \left(\frac{1}{f_{\text{low}}^2} - \frac{1}{f_{\text{high}}^2} \right)$$

From LIGO/Virgo measurement (Abbott et al. 2017):

Currently allowed region : $\lambda_g > 1.6 \times 10^{13}$ km

If we detect no dispersion, i.e.

If $\Delta t < 0.5$ day, then

$$\lambda_g > 1.4 \times 10^{14} (D/100 \text{ Mpc})^{1/2} \text{ km}$$

Summary

- Astrophysical models allow binary black holes to form inside $10 R_s$ of SMBHs (Chen & Han 18)
- Gravitational-wave forms affected by redshift (Chen, Li, & Cao17)
- Multi-band gravitational wave sources
- Test recoil, mass loss, and alternative gravity models (Han & Chen 19)
